**An introduction to Na^+ , Ca^{2+} , and Mg^{2+}
in health and disease**

Tour along the nephron

The kidney controls body fluid volume and osmolality

Sodium (Na^+), calcium (Ca^{2+}) and magnesium (Mg^{2+}) play crucial roles in the normal functioning of cells and organs [1-3]. Careful maintenance and regular monitoring of these electrolyte levels is essential for proper function of cells. Na^+ , Ca^{2+} and Mg^{2+} balances are tightly maintained by regulating their absorption in the intestine, exchange from bone, and reabsorption and secretion by the kidneys [4-6].

The functional unit of the kidney is the nephron, which consists of the corpuscle and tubule [7]. A renal corpuscle functions as the blood-filtering component and is build up by the glomerulus and Bowman's capsule [8]. Small molecules, water, and metabolic waste can be filtered through the glomerulus, but large molecules like proteins (>45 kDa) will remain in the blood. The filtrate flows through the renal tubule where electrolytes will be reabsorbed or secreted. Nearly 97% of the filtered Na^+ , Ca^{2+} and Mg^{2+} will be reabsorbed along the nephrons. They consist of several distinct functional and anatomical parts where all of the Na^+ , Ca^{2+} and Mg^{2+} reabsorption take place: the proximal tubule (PT); the thick ascending limb of loop of Henle (TAL); the distal convoluted tubule (DCT); the connecting tubule (CNT), and collecting duct (CD) (Figure 1).

Segments along the nephron

The proximal tubule

The PT is the first segment of the nephron and is also the major site for Na^+ and Ca^{2+} reabsorption [9, 10]. It is divided into three parts, S1, S2 and S3. In the early PT (S1 and S2), large amounts of filtered amino acids, phosphate, glucose, lactate, and citrate will be reabsorbed [11, 12]. Approximately 65% of the Na^+ will be reabsorbed in the PT, mainly through passive paracellular or active transcellular pathways [13]. The sodium-glucose transporter (SGLT), sodium-dependent phosphate cotransport protein (NaPi-2a) and sodium-hydrogen exchanger 3 (NHE3) are the predominant apical transporters that are responsible for the transport of Na^+ in the PT [14-18]. The intracellular Na^+ concentration must be kept low to facilitate Na^+ -coupled co-transport. The basolateral sodium/potassium ATPase (Na^+/K^+ -ATPase) pumps three Na^+ ions out of the cell and transports two K^+ ions back into the cell [19]. Nearly 60-70% of the filtered Ca^{2+} will also be reabsorbed in the PT [20]. Na^+ reabsorption coincides with passive water reabsorption. The Na^+ -driven water movement can increase the concentration of Ca^{2+} in the lumen, which will drive passive Ca^{2+} diffusion through the tight junctions of epithelial cells into the renal interstitium. Only 10-25% of filtered Mg^{2+} is reclaimed in the PT [21] (Figure 1).

Figure 1. Na⁺, Ca²⁺ and Mg²⁺ reabsorption along the nephron.

Around 95-99% of Na⁺, Ca²⁺ and Mg²⁺ in the filtered pro-urine is reabsorbed along the nephron in the proximal tubule (PT), thick ascending limb of loop of Henle (TAL), distal convoluted tubule (DCT), connecting tubule (CNT), and the collecting duct (CD). The remaining Na⁺, Ca²⁺, and Mg²⁺ will be excreted with urine. TDL, the descending loop of Henle.

The loop of Henle

The loop of Henle consists of a descending limb and an ascending limb (Figure 1). The descending loop of Henle (TDL) is permeable to water because of the water channel aquaporin 1 (AQP1), but impermeable to electrolytes [22-24]. Vice versa, the TAL is impermeable to water, but it is permeable to electrolytes [25]. The TAL is responsible for roughly 25% of the filtered Na⁺ reabsorption. In addition, it is also a crucial segment for Mg²⁺ and Ca²⁺ reabsorption [4, 26, 27], taking in about 20-25% of filtered Ca²⁺, and 50%-70% of filtered Mg²⁺ by paracellular processes [28, 29].

The PT reabsorbs bulk of filtrated Ca²⁺ via the paracellular pathway. Subsequently, Ca²⁺ is passively reabsorbed in the TAL. Here, the driving force for paracellular cation transport is a lumen-positive transepithelial voltage, which is mainly generated by the sodium-potassium-chloride cotransporter (NKCC2) and the renal outer medullary potassium channel (ROMK) [27]. The calcium sensing receptor (CaSR) can regulate this transport without changing the transepithelial voltage [30]. Studies have shown that CaSR can regulate Ca²⁺ reabsorption by inhibiting the activity of ROMK or by affecting tight junction permeability [31, 32]. Impaired regulation of Ca²⁺ transport in the TAL can result in several diseases, such as hypocalcemia, hypercalcemia, or kidney stone disease.

The reabsorption of the divalent cations such as Mg^{2+} and Ca^{2+} mainly depends on tight junction permeability in this segment. Claudin proteins are the crucial constituents of the tight junction complexes [33]. The claudin family has 24 members. Some claudin family members play fundamental roles in forming impermeable barriers, while others modulate the permeability to small molecules and electrolytes [34–36]. Claudins 3, 10b, 11, 14, 16, and 19 are specifically localized in the TAL [36–38]. The tight junctions formed by claudins 16 and 19 are highly permeable to Mg^{2+} and Ca^{2+} [39], while the tight junctions made by claudin 10b are highly permeable to Na^+ [40, 41]. Mutations in *CLDN16* (claudin 16) and *CLDN19* (claudin 19) can result in familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC) [42–45]. Recently, several studies showed that increased plasma Ca^{2+} and Mg^{2+} levels can alter the tight junctions by causing them to incorporate claudin 14 in the structure which will shift the preference from divalent cations such as Ca^{2+} and Mg^{2+} towards monovalent ions like Na^+ [31, 46].

The distal convoluted tubule connecting tubule

The DCT is responsible for 3–8% of Na^+ reabsorption [47]. It has two parts, namely an early segment and a late segment, also known as DCT1 and DCT2, respectively [48]. The key player in Na^+ reabsorption is the thiazide-sensitive sodium-chloride co-transporter (NCC) on the apical side of DCT1 cells [49]. Additionally, the epithelial sodium channel (ENaC) also participates in Na^+ reabsorption in DCT2 and CNT [50].

Approximately 1–10 % of filtered Mg^{2+} is reabsorbed in the DCT1 [50]. The transient receptor potential cation channel subfamily M, member 6 (TRPM6) plays a crucial role in epithelial Mg^{2+} transport in the kidney [51]. Recessive *TRPM6* mutations cause disturbances in intestinal Mg^{2+} absorption and urinary Mg^{2+} wasting which lead to severe hypomagnesemia [52, 53]. Several other proteins may play roles in transporting Mg^{2+} across the basolateral membrane, such as solute carrier family 41 member 1 (SLC41A1) and solute carrier family 41 member 3 (SLC41A3). Knocking down *slc41a1* caused renal Mg^{2+} wasting in zebrafish larvae [54]. In another study, *Slc41a3* knockout mice exhibit low serum Mg^{2+} levels [55].

The DCT2 and CNT reabsorb nearly 10% of the filtered Ca^{2+} [50]. Unlike other segments of the nephron, Ca^{2+} reabsorption in the DCT and CNT occurs by active transcellular mechanisms. The apical transient receptor potential channel subfamily V member 5 (TRPV5) plays a key role in transepithelial Ca^{2+} transport [56]. *Trpv5* knockout mice exhibited urinary Ca^{2+} wasting [56]. In addition, Ca^{2+} -binding protein calbindin- $\text{D}_{28\text{K}}$, which is used to buffer intracellular Ca^{2+} levels [57], carries Ca^{2+} to the basolateral surface. Then, the plasma membrane calcium-ATPase (PMCA) and type 1 sodium/calcium exchanger (NCX1) work together to extrude Ca^{2+} to the extracellular space [58].

The collecting duct

The CD is the final part of the kidney to regulate the fluid balance and electrolytes [59, 60]. The CD extends all the way from the cortex to the medulla section of the kidney and the

DCT and the ureter are connected by the CD. Nearly 1% of filtered Na^+ is reabsorbed in the collecting duct. The CD plays a very minimal role in the reabsorption of Ca^{2+} and Mg^{2+} [61]. Under normal conditions, CD is slightly permeable to Na^+ . Filtered Na^+ is diffused through the apical side of CD by ENaC. Then, the $\text{Na}^+-\text{K}^+-text{ATPase}$ on the basolateral side will extrude the Na^+ to the interstitial space [62-64]. Any remaining Na^+ , Ca^{2+} and Mg^{2+} will be excreted in the urine by the kidney.

Na^+ handling in diabetes and hypertension

Na^+ transport in the proximal tubule

Disturbed Na^+ and glucose reabsorption in the PT typically leads to Na^+ and glucose disorders and subsequent hypertension and diabetes, since the PT is the main segment for Na^+ and glucose reabsorption in the kidney. SGLT2 is a key transporter for Na^+ and glucose reabsorption in the PT [65].

Figure 2. Glucose and Na^+ reabsorption in the proximal tubule.

Na^+ and glucose reabsorption through SGLT2 in the proximal tubule epithelial cell. G, glucose; SGLT1, sodium-glucose co-transporter 1; GLUT1, glucose transporter 1; SGLT2, sodium-glucose co-transporter 2; GLUT2, glucose transporter 2; S1/2, segment 1/2; S3, segment 3.

Na^+ and glucose transport in the proximal tubule in diabetes and hypertension

Type 2 diabetes is characterized by increasing blood glucose levels [66] due to insulin resistance. It is a worldwide epidemic and the number of people affected is projected to rise beyond 600 million in the next 25 years, which equals over 10% of the adult population, with equal rates in both men and women [67]. Type 2 diabetes is also the leading cause of nephropathy [68, 69]. In humans, the kidneys filter approximately 180 grams of D-glucose from plasma each day, and this is normally reabsorbed in the kidney [70]. SGLT1 (*SLC5A1*) and SGLT2 (*SLC5A2*), which are encoded by genes from the solute carrier 5A family, are crucial regulators in intestinal and renal glucose handling [71]. Other transporters that are involved in the glucose maintenance are the facilitative glucose transporters: glucose transporter 1 (GLUT1) and glucose transporter 2 (GLUT2) [72]. SGLT2 reabsorbs approximately 90% of the glucose from the lumen of the S1/S2 segment of the PT [73], while GLUT2 transports glucose across the basolateral membrane (Figure 2) [74]. The remaining glucose is reabsorbed in the S3 segment, through the coordinated actions of SGLT1 and GLUT1 [71]. Mutations in the *Sglt1* gene result in glucose-galactose malabsorption and impaired glucose transport [75]. Mutations in *Sglt2* gene can cause familial renal glycosuria, characterized by decreased renal tubular glucose reabsorption [76, 77]. The *Sglt2* knockout mice exhibited attenuated hyperglycemia and glomerular hyperfiltration [78]. Increased expression and activity of SGLT2 resulted in increased glucose reabsorption, which causes hyperglycemia in diabetes patients [79, 80].

More than two-thirds of patients with type 2 diabetes have concomitant hypertension and salt and water retention [81, 82]. Hypertension in these patients increases their already elevated cardiovascular risks [83, 84]. Recent interest in the kidneys as a target for glucose control in diabetes has important implications for blood pressure management. Na^+ retention has been implicated in the pathophysiology of hypertension in type 2 diabetes and in impaired vasodilatory responsiveness to angiotensin-I-converting enzyme (ACE) inhibition [85, 86]. Pharmacological inhibition of SGLT2 transporters improves glucose control by inducing glucosuria, but these inhibitors also lower blood pressure to a degree comparable with the use of thiazide diuretics [87, 88]. Studies showed that SGLT2 inhibitors increase Na^+ delivery to macula densa, then, juxtaglomerular apparatus sense this increased Na^+ delivery as an elevation in the filtrate volume which leads to afferent vasoconstriction, a reduction in intraglomerular pressure and a suppressed glomerular filtration rate (GFR) [89-91]. Recently, Woods and his colleagues reported that SGLT2 inhibitor canagliflozin decreases mRNA and protein level of renal angiotensinogen and reduced blood pressure in animal models with type 2 diabetes [92]. This suggests that SGLT2 inhibitors may reduce blood pressure through suppressing renin-angiotensin-aldosterone system (RAAS). Co-inhibition of glucose-coupled Na^+ transport may be the driving force behind this blood pressure lowering effect, the effect of which may be mediated by the action of Na^+ transporters located in the local or more distal part of the nephron.

Hypercalciuria in kidney stone disease

Ca²⁺ handling in the Henle's loop

The urinary Ca²⁺ concentration in the loop of Henle is an important factor in the formation of kidney stone. The loop of Henle serves to concentrate pro-urine [93]. Since no water is reabsorbed at this segment, there is a 10-fold or even higher increase in osmolality which results in urinary 'supersaturation' with poorly soluble waste salts such as Ca²⁺-phosphate (CaP) and Ca²⁺-oxalate (CaOx). CaP and CaOx are the major components for crystal formation [94]. In this segment, the pathophysiology of kidney stones will be discussed.

Hypercalciuria

Urinary Ca²⁺ excretion greater than 300 milligrams (mg) per day for men and greater than 250 mg per day in women is considered as hypercalciuria [95, 96]. Conditions known to cause hypercalciuria include: *i)* diet, such as excessive dietary intake of Ca²⁺, Na⁺, carbohydrates, animal protein, alcohol, and reduced intake of phosphate and potassium, *ii)* increased intestinal Ca²⁺ absorption, *iii)* reduced renal tubular reabsorption of Ca²⁺, and *iv)* increased osteoclastic bone reabsorption [97-99]. Remarkably, a large percentage of patients have idiopathic hypercalciuria, with no explanation for the increased urinary Ca²⁺ levels [99, 100]. Hypercalciuria is considered a risk factor for Ca²⁺ crystal deposition in the kidneys, which can ultimately result in kidney stone formation (nephrolithiasis). This occurs by at least two mechanisms: first, by increasing the concentration of urinary Ca²⁺ salts (CaP and CaOx), and second, urinary Ca²⁺ binds stone inhibitors such as citrates, leading to a reduction in the activity of this inhibitor [101].

Nephrolithiasis

Nephrolithiasis is a highly widespread urologic disease with prevalence rates ranging from 7-13% in North America, 5-9% in Europe and 1-5% in Asia [102]. The prevalence of kidney stones has increased worldwide over the last four decades, with the prevalence in women rising disproportionately compared to men [103]. This growing trend is considered to be associated with lifestyle changes such as lack of physical activity and altered dietary habits [104]. Medical management of urinary stones includes pharmacological interventions, minor endourological intervention for stone removal, and extracorporeal shock wave lithotripsy [105]. They are highly effective but are associated with some serious side effects and without complete preventing of the recurrence of kidney stones [105]. There is currently no effective drug on the market to cure or prevent kidney stone recurrences. Without proper treatment, the rate of the secondary stone formation ranges from 10% in the first year up to 75% in 20 years [106, 107]. The high prevalence and recurrent nature of kidney stones make it a substantial economic burden. In addition, kidney stone disease is associated with an increased rate of chronic kidney disease, end-stage renal

failure, hypertension, and myocardial infarction [104, 108]. These results suggest that the emphasis should not only be placed on finding new treatments for kidney stones, but also on finding a new method to prevent stone formation in high risk groups and recurrent in kidney stone patients.

Pathophysiology of kidney stones

Biochemically, there are different types of stones depending on the type of abnormalities in urine composition. Ca^{2+} stones are the most common type of renal stones, compromising about 80% of all kidney stones [109]. The formation of kidney stones is a multifactorial process that involves intrinsic factors such as age, sex, genetic predisposition, and extrinsic factors such as geography, diet, and water intake [110]. The pathogenesis of kidney stones is still not completely understood. They often begin from a foundation called Randall's plaque present at the renal papillary surface, but there are several steps involved in the formation of stones [108]. Step 1: Urine supersaturation. In this phase, the supersaturation is the result of the excretion of poorly soluble minerals such as CaP or CaOx in a relatively small volume of urine [108]. Step 2: Nucleation. The free atoms, ions, or molecules in the supersaturated urine begin to form microscopic clusters [104]. Step 3: Crystal growth and crystal aggregation. The preformed crystals stick together and form a hard rock mass. These small hard mass of stones stay together and form a larger stone in a process called crystal aggregation. Crystal aggregation results in more nucleation sites, leading to a snowball effect [104]. Step 4: Crystal-cell interaction. At this stage, the formed crystals adhere to the lining of the epithelial cells in the renal tubules [104]. This process results in oxidative stress leading to cell damage and cell membrane rupture. The damaged cells can then invert their cell membrane, allowing close contact between the anionic side of the cell and the urine. This interaction results in crystal bonding at that location. Step 5: Crystal retention and stone formation. At this stage, the formation of kidney stones depends on the presence of promoting and inhibiting molecules in the urine (Figure 3) [104]. All of the steps are crucial for the formation of stones. Researchers have shown that urine contains small molecules such as citrate and pyrophosphate, and macromolecules such as glycoproteins, glycosaminoglycans, and proteoglycans can alter and inhibit the formation of stones [110-116]. Abnormalities in the structure or function of these molecules have been identified in recurrent kidney stone patients [104, 108]. Theoretically, Ca^{2+} -containing kidney stones can be prevented by increasing physiological inhibitory molecules such as nephrocalcin (NC), Tamm-Horsfall protein (THP), and osteopontin (OPN) or by reducing the urinary Ca^{2+} concentration [117-121]. NC is a Ca^{2+} -binding glycoprotein and one molecule of NC can bind to four molecules of Ca^{2+} [122]. NC is able to inhibit the nucleation phase, Ca^{2+} oxalate monohydrate (COM) crystal growth, crystal aggregation and crystal adherence to renal tubules [120, 122]. THP is a strong crystal aggregation inhibitor that is reported to significantly reduce COM crystal endocytosis [123]. This indicates that THP may prevent the COM crystals uptake by the

distal tubular epithelial cells of the kidney and thereby inhibit renal crystal retention and urolithiasis [124]. OPN plays a crucial role in inhibiting the nucleation step and CaOx crystal growth and aggregation phase [125]. What is more, OPN is able to direct CaOx crystallization to the CaOx dihydrate phase instead of CaOx monohydrate phase [126]. Hypercalciuria is present in about 40 to 60% of all patients with kidney stones [127]. Therefore, targeting urinary Ca^{2+} is an appealing intervention that should be further investigated in the future.

Figure 3. Mechanisms of kidney stone formation.

The process of kidney stone formation includes several steps such as urine supersaturation, nucleation, crystal growth and crystal aggregation, crystal-cell interaction and crystal retention and stone formation.

Fine tuning of Mg^{2+} reabsorption

Mg^{2+} transport in the distal convoluted tubule

The DCT reabsorbs nearly 10% of the filtered Mg^{2+} in the kidney [128]. There is no Mg^{2+} reabsorption beyond the DCT. Mg^{2+} reabsorption is tightly controlled by the Mg^{2+} transporters, channels, and sensors in the DCT [4, 5, 129]. However, it is still not totally understood how these transporters, channels, and sensors mediate the Mg^{2+} influx and efflux. In 2011, patients carrying mutations in *CNNM2*, which encodes cyclin and CBS domain divalent metal cation transport mediators (CNNM2), were found to suffer from hypomagnesemia [130]. Later studies demonstrated that CNNM2 is involved in Mg^{2+} transport in the kidney [131, 132]. In this segment, the structure and molecular function of CNNMs and a novel urinary Mg^{2+} excretion related gene, *Ar15*, will be described.

Domain distribution of CNNMs

CNNM (1-4) proteins are also known as ancient conserved domain proteins (1-4) and share homology with cyclins. However, the function of CNNMs in the cell cycle has not been identified. Structurally, CNNMs possess four different domains that are combined by linkers [132] (Figure 4). The extracellular amino (N)-terminal domain which contains a conserved N residue (N112 in CNNM2, N73 in CNNM3 and N85 in CNNM4) is crucial for glycosylation. This glycosylation site is also important for cell surface expression [132]. After the N-terminal domain is a domain of unknown function-21 (DUF21) that crosses the plasma membrane three times [132]. The cytosolic cystathionine β -synthase (CBS)

domains, known as the 'Bateman module', consist of two consecutive CBS motifs [132]. As with most CBS domain proteins, the Bateman modules of CNNMs interact with each other. The CBS2 domain of CNNMs contains an extended loop that makes this Bateman motif in CNNMs different from the Bateman motifs discovered in other proteins [133-135].

Figure 4. Structural overview of CNNM.

A, Linear model of CNNMs, showing the four color-coded independent domains. Extracellular domain is indicated in dark blue, DUF21 transmembrane domain is indicated in orange, Bateman domain is indicated in light blue and CNBH domain is indicated in light green, the remaining part is the intracellular carboxyl (C)-terminal tail (C-tail). B, Structure of CNNMs, with color-coded domains matching with A. DUF21, domain with unknown function 21. CNBH, cyclic nucleotide monophosphate-binding homology domain (Figure adapted from [135]).

This extended loop plays a crucial role in interacting with other proteins. Studies showed that phosphatase of the regenerating liver (PRLs) bind to the extended loop of the CBS2 domain of CNNM3 to mediate intracellular Mg^{2+} levels [136, 137]. The CBS domains are followed by a cyclic nucleotide monophosphate-binding homology domain (CNBH) and an unstructured carboxyl (C)-tail [132].

Organ distribution and localization of the CNNM protein family

The tissue distribution and expression pattern of the CNNMs are quite diverse [130, 132, 138, 139]. CNNM1 functions as a copper chaperone or storage protein that is mainly expressed in the brain. Northern blots revealed that CNNM1 is moderately expressed in the testis and very low expression levels of CNNM1 have also been detected in the stomach, small intestine, colon, spleen, heart, lungs, liver, kidney, and skeletal muscles [138]. CNNM2 is ubiquitously expressed in the body and is highly expressed in the kidney, brain, liver, and heart. CNNM2 is localized in the TAL and DCT of the kidney [130]. CNNM3 is also ubiquitously present but has the highest expression in the brain, lung, spleen, and heart. It is moderately expressed in the liver, colon, lung, testis, and placenta. However, little expression is detected in skeletal muscles or small intestine [132, 140]. CNNM4 is abundant in the heart, kidney, lung, placenta, testis, and intestinal tract [132, 140]. CNNM4 expression can also be detected in the epididymis and sperm [141].

Importance of CNNM2 in regulating Mg^{2+} homeostasis

In 2011, Stuiver *et al.* reported that renal Mg^{2+} reabsorption is disturbed in patients carrying CNNM2 mutations [130]. Later, Arjona *et al.* identified five new mutations in CNNM2 in five families suffering from intellectual disability, seizures, and hypomagnesemia [142]. Interestingly, CNNM2 mutations (except for p.L330F) identified in the hypomagnesemic patients resulted in significantly decreased $^{25}Mg^{2+}$ uptake in HEK293 cells [142]. Cnnm2-knockdown zebrafish exhibited neurodevelopmental impairments, weak touch-evoked escape behavior, and decreased total body Mg^{2+} content [142]. These phenotypes were rescued by injecting mammalian wildtype cnnm2 cRNA [142]. Similar studies investigating the function of CNNM2 in Mg^{2+} homeostasis have also been performed by using Cnnm2 heterozygous (Cnnm2^{+/-}) mice and kidney-specific knockout mice [131]. Homozygous Cnnm2 knockout mice died during embryonic development [131]. Compared with Cnnm2 wildtype (Cnnm2^{+/+}) mice, Cnnm2^{+/-} mice exhibited lower serum Mg^{2+} levels. However, urinary and fecal Mg^{2+} excretion in Cnnm2^{+/+} mice and Cnnm2^{+/-} mice did not differ significantly [131]. Cnnm2 kidney-specific knockout mice demonstrated a decrease in serum Mg^{2+} level [131]. Collectively, all of these results suggest that CNNM2 plays a crucial role in maintaining the Mg^{2+} balance.

Regulation of CNNMs localization and activity by CNNM ligands and interacting partners

Studies have indicated that ligands and CNNM binding partners can modify the cellular localization and activity of CNNM proteins [136, 137, 143]. For example, clathrin adaptor protein (AP) complex-1 mediates the localization of CNNM4 at the basolateral membrane [144]. Mutations of three dileucine motifs (L575/576, L758/759, and L765/766) in the CNBH domain of CNNM4 abrogated CNNM4 basolateral localization and CNNM4's interaction with AP-1A and AP-1B [144].

The activity of CNNMs can also be regulated by either small ligands such as Mg²⁺ and ATP or proteins. Hirata *et al.* first found the direct binding of ATP to the Bateman module of CNNM2 by surface plasmon resonance (SPR) [137]. ATP binding assays demonstrated that this binding is Mg²⁺ dependent since the binding affinity of the CBS domain for ATP is stronger in the presence of Mg²⁺ than the conditions when Mg²⁺ is absent [137].

In 2014, two different groups separately reported that CNNMs interact with the PRLs to regulate intracellular Mg²⁺ concentration [136, 137]. PRL has three members: PRL1, 2, and 3, which are highly expressed in a large number of cancers [145, 146]. Binding between CNNM3 and PRL-2 is important for breast cancer cell proliferation and tumor growth, and inhibition of this binding can hinder human breast cancer cell proliferation [147]. Later studies revealed that all PRL family members bind to CNNMs (CNNM1-4), and truncated CNNM3 mutagenesis studies showed that the CBS domain plays a fundamental role in forming the complex [136, 143]. Moreover, the highly conserved D558 residue, which is localized at the extended loop of the CBS2 motif of CNNM2, was found to play a determinant role in forming the CNNM/PRL complex [134]. This conserved residue act as a pseudosubstrate of PRL and their binding inhibits Mg²⁺ efflux [134, 136].

ARL15 as a novel gene in renal Mg²⁺ handling

ADP ribosylation factor like GTPase 15 (ARL15), which is a member of the GTP-binding proteins, plays a crucial role in renal Mg²⁺ handling [148]. Recently, Corre *et al.* reported that ARL15 influences renal Mg²⁺ reabsorption through regulating the activity of the epithelial Mg²⁺ channel TRMP6 [148]. The T46N ARL15 mutant, which was predicted to possess a dominant negative nature, failed to increase TRPM6 channel activity [148]. Immunohistochemistry results indicated that ARL15 is highly expressed in the TAL and DCT [148]. In their zebrafish model, *arl15* knockdown resulted in increased urinary Mg²⁺ excretion. ARL15 is shown to be mainly localized in the Golgi, but it is also expressed in the plasma membrane and intracellular vesicles in 3T3-L1 cells [149]. This indicates that ARL15 might be involved in vesicular trafficking and posttranslational modification [149].

A genome-wide association study (GWAS) showed that ARL15 is associated with low serum adiponectin levels, lipid levels, fasting insulin levels, and type 2 diabetes [150]. Rocha *et al.* reported that the *Arl15* mRNA expression level was significantly increased with the process of adipogenesis in 3T3-L1 adipocytes. Knocking down *Arl15* expression significantly impaired 3T3-L1 preadipocyte differentiation and droplet formation [149]. Moreover, decreased mRNA expression levels of adiponectin and reduced secretion of adiponectin in 3T3-L1 adipocytes were demonstrated in *Arl15* knockdown cells [149]. However, *Arl15* knockdown does not affect insulin-signaling and glucose uptake, suggesting that the function of ARL15 may be restricted to adiponectin secretion and adiponectin vesicle trafficking [149].

Outline of this thesis

The aim of this thesis is to get insight into the role of Na^+ , Ca^{2+} , and Mg^{2+} transporters in diseases such as diabetes, hypertension, kidney stone disease, hypomagnesemia, and renal carcinoma. Although much is known about the (patho) physiology of these diseases, little is known about the molecular mechanisms underlying these transport disorders in the kidney. **Chapter 2** provides new insights into renal Na^+ -glucose handling. Diabetic mice were treated with dapagliflozin, an SGLT2 inhibitor, and the expression of Na^+ transporters in the kidney was investigated. This study will help us to better understand the effect of dapagliflozin treatment on the local and downstream Na^+ transporters in the kidney. In **Chapter 3**, we studied an out-of-the-box idea to prevent kidney stone formation. Based on the literature on the Ca^{2+} -binding loop of EF-hand proteins, several small peptides (20-30 residues) were developed and analyzed for their Ca^{2+} -binding affinity. To assess the efficacy of such peptides *in vivo*, we aimed to generate a kidney stone mouse model. This study provides the first step towards testing a novel approach to the treatment and prevention of kidney stones. In **Chapter 4**, we investigated the role of ARL15 in Mg^{2+} homeostasis. ARL15 expression and tissue distribution were investigated. *Arl15^{+/-}* mice were generated to investigate its role in renal Mg^{2+} handling by analyzing urine and serum Mg^{2+} levels, as well as the expression of renal Mg^{2+} -related genes. In **Chapter 5**, the functional relevance of binding between ARL15 and CNNMs was outlined. Proximity-dependent biotin identification, affinity-purification/mass spectrometry, and co-immunoprecipitation were used to investigate the binding of ARL15 to CNNMs proteins. Furthermore, ARL15-mediated CNNMs' cell surface expression and Mg^{2+} transport activities were studied in various types of renal cell carcinoma cell lines. These findings revealed a novel regulatory mechanism of Mg^{2+} transport within the DCT, which will help to understand the regulation of Mg^{2+} handling in this segment. Finally, the findings from the studies of this thesis are discussed and summarized in **Chapter 6 and 7**.

Nephron Clin Pract. 2019 May; 142(1): 51–60

Abstract

Inhibition of the sodium/glucose co-transporter 2 (SGLT2) is a new therapeutic strategy for diabetes. It is unclear how proximal loss of sodium (Na^+) (and glucose) affects the subsequent Na^+ transporters in the proximal tubule (PT), thick ascending limb of loop of Henle (TAL), distal convoluted tubule (DCT), and collecting duct (CD). Mice on a high fat diet were administered 3 doses streptozotocin (STZ) 6 days prior to oral dapagliflozin administration or vehicle for 18 days. A control group of lean mice were also included. Body weight and glucose were recorded at regular intervals during treatment. The expression of renal Na^+ transporters in nephron segments were analyzed by RT-qPCR and Western blot. Dapagliflozin treatment resulted in a significant reduction in body weight and blood glucose compared to vehicle treated controls. mRNA results showed that sodium-hydrogen antiporter 3 (*Nhe3*), solute carrier family 34 member 1 (*Slc34a1*) and sodium channel epithelial 1 subunit alpha (*Scnn1a*) expression was increased, Solute carrier family 8 member 1 (*Slc18a1*), sodium channel epithelial 1 subunit beta (*Scnn1b*) and sodium channel epithelial 1 subunit gamma (*Scnn1g*) expression declined, respectively, in dapagliflozin-treated mice when compared with saline vehicle mice. Solute carrier family 12 member 1 (*Slc12a1*) and solute carrier family 12 member 3 (*Slc12a3*) mRNA expression were not affected by dapagliflozin treatment. ATPase, sodium-potassium transporting, beta 1 polypeptide (*Atp1b1*) expression was also increased significantly by dapagliflozin treatment, but it did not affect ATPase, sodium-potassium transporting, alpha 1 polypeptide (*Atp1a1*) and solute carrier family 2 member 2 (*Slc2a2*) expression. Western blot analysis showed that sodium-phosphate cotransporter (NaPi-2a), NHE3 and sodium-potassium-ATPase subunit beta 1 (Na^+ - K^+ -ATPase β 1) expression was up-regulated in dapagliflozin-treated diabetic mice when compared with saline vehicle mice. Our findings suggest that dapagliflozin treatment augments compensatory changes in the renal PT in diabetic mice.

Introduction

Type 2 diabetes mellitus (T2DM) is a major health problem affecting 415 million people worldwide [1, 2]. This represents 8.3% of the adult population, with equal rates in women and men [3]. From 2012 to 2015, approximately 1.5 to 5.0 million deaths each year resulted from diabetes [4]. Diabetes and hypertension frequently occur together [5]. Hypertension in these patients further increases their already elevated cardiovascular risks, yet is difficult to manage. Indeed, in about half of the diabetic population, blood pressure targets are not met despite the use of multiple blood pressure lowering drugs, including diuretics [6-8].

Recently, dapagliflozin, a SGLT2 (SLC5A2) inhibitor, was introduced as a novel class of glucose-lowering agents for the treatment of type 2 diabetes. As SGLT2 is responsible for approximately 90% of the filtered glucose reabsorption in the PT segment 1 and 2 (S1/2) [9-11], its inhibition reduces renal glucose and Na⁺ reabsorption, leading to urinary glucose excretion and a reduction in blood glucose levels [12]. Therefore, dapagliflozin is considered to be an efficient and novel drug to treat patients with T2DM [13-16].

Some studies have also demonstrated that SGLT2 inhibitors exhibit an impressive diuretic effect and consequent blood pressure reduction, whereas others described modest effects on volume status [17-20]. SGLT2 inhibition reduces Na⁺ reabsorption in the PT and thereby increases the distal tubular Na⁺ load, which inhibits the renin-angiotensin-aldosterone system (RAAS) activation [21]. The kidneys efficiently reabsorb 99% of filtered Na⁺ by the combined action of: *i*) the PT where 60-70% is reabsorbed via NHE3, SGLT1 and SGLT2 [22]; *ii*) the TAL that is responsible for 15-25% reabsorption via paracellular routes and NKCC2; *iii*) the DCT that reabsorbs 15-25% via the thiazide-sensitive NCC [23]; *iv*) the CD where the Epithelial sodium channel (ENaC) facilitates the reabsorption of the remaining 1-2% [10, 24].

A recent study has found that treatment with an SGLT2 inhibitor increases the expression of medullary transport proteins [1]. However, a systematic analysis of the compensatory mechanisms that regulate renal Na⁺ reabsorption after SGLT2 treatment is lacking. Knowledge of which nephron segment compensates for proximal Na⁺ loss is of great fundamental and clinical interest, as this would provide the major pharmacological target for antihypertensive treatment.

Therefore, the purpose of this study was to identify the compensatory impact of proximal Na⁺ wasting by the SGLT2 inhibitor, dapagliflozin, on renal Na⁺ transporters in high fat diabetic mice.

Methods and materials

Animal model

Adult male Swiss mice (Harlan, Oxon, UK) at 16 weeks of age were housed in an air-conditioned room at $22\pm 2^{\circ}\text{C}$ with 12:12 h light/dark cycle. Mice had free access to high fat diet (45% AFE Fat; Special Diet Services, Witham, UK; total energy 26.15 kJ/g). An additional lean group had free access to standard rodent chow (Teklad Global 18% Protein Rodent Diet; Harlan, UK; total energy 13.0 kJ/g). All animals were free to access drinking water and respective diet, and no adverse effects were observed during the entire experimental study. All experiments were performed according to the principles of Laboratory Animal Care (NIH publication no. 86-23, revised 1985) and UK Home Office Regulations (UK Animals Scientific Procedures Act 1986).

Experimental treatments

Mice commenced high fat diet on day -20 and remained on this diet for the duration of the study. On day -6, streptozotocin (50 mg/kg; i.p; Sigma-Aldrich, Dorset, UK) freshly prepared in ice-cold 0.1 M Na^+ citrate buffer (HCl/pH 4.5) was administered 3 doses in total over a period of 6 days to induce diabetes. On day 0, one group of high fat mice ($n=8$) commenced daily treatment with dapagliflozin (1 mg/kg; p.o.; Stratch Scientific Ltd., Suffolk, UK) for 18 days whereas high fat control group ($n=8$) received saline vehicle (0.9% w/v NaCl; p.o.) once-daily for the same time period. The volume for the oral gavage was 100 μL . A diagrammatic representation of the experimental design is shown in Figure 1.

Quantitative analyses of gene expression

At study termination, total RNA was extracted from mouse kidney tissues with Trizol (Invitrogen, Carlsbad, CA, USA) in accordance with the manufacturer's protocol.

Subsequently, mouse RNA samples were subjected to DNase treatment (Invitrogen, Breda, The Netherlands) to prevent genomic DNA contamination and the reverse transcriptase reaction was subsequently performed to synthesize cDNA [25]. mRNA levels of the target genes were determined by relative RT-qPCR following the MIQE guidelines 20 with a CFX96TM real-time PCR detection system (Bio-Rad Laboratories, Hercules, CA, USA) using iQTM SYBR Green Supermix (Bio Rad) detection of single PCR product accumulation. Each group had 8 kidneys and RT-qPCR experiments were commenced in triplicate. All primers for *Slc5a2*, *Slc5a1*, *Nhe3*, *Slc34a1*, *Slc12a1*, *Slc12a3*, *Slc18a1*, *Scnn1a*, *Scnn1b*, *Scnn1g*, *Atp1a1*, *Atp1b1*, *Slc2a2*, and *Gapdh* were purchased from Biolegio BV (Nijmegen, Netherlands). In this study, gene expression levels were normalized to the expression levels of the standard species-specific reference genes glyceraldehyde 3-phosphate dehydrogenase (*Gapdh*). Relative mRNA expression was analyzed using the Livak method ($2^{-\Delta\Delta\text{Ct}}$). Primer sequences are shown in Table 1.

Figure 1. Timeline for the experimental study.

Group 1 (lean control), lean mice on normal diet for 38 days. Group 2 (high fat controls), mice commenced a high fat diet on day -20 and subsequently received STZ treatment on day -6. At day 0, saline vehicle was administered for 18 days. Group 3 (high fat dapagliflozin), mice commenced high fat diet on day -20 and subsequently received STZ on day -6. At day 0, dapagliflozin was administered for 18 days. STZ, streptozotocin; Lean, lean control mice; HFD, high fat diet treatment mice; DAPA, dapagliflozin treated mice.

Buffers

Lysis buffer: 150 mM NaCl, 50 mM Tris-HCl (pH 7.5), 1 mM EDTA, 1 mM EGTA, 1 mM sodium-orthovanadate, 1% (v/v) Triton X-100, 10 mM sodium-glycerophosphate, 50 mM sodium fluoride, 0.27 M sucrose, 10 mM sodium pyrophosphate, containing freshly added tablet of complete protease inhibitor cocktail (Roche, Basel, Switzerland) and 0.1% (v/v) β -mercaptoethanol. SDS-PAGE sample buffer: 5x 10% (w/v) SDS, 10 mM β -mercaptoethanol, 50% (v/v) glycerol, 0.3 M Tris-HCl (pH 7.5), 0.05% (w/v) bromophenol blue. TBS-T (Tris-buffered saline, 0.1% (v/v) Tween 20): Tris-HCl (200 mM, pH 7.5), 0.15 M NaCl, and 0.2% (v/v) Tween-20.

Immunoblotting

Kidney tissues were isolated from mice and homogenized in ice cold lysis buffer. The kidney lysates were clarified by centrifugation at 4°C for 15 minutes at 16,110 g and supernatants were stored at -80°C. Protein concentrations were measured by performing a Bicinchoninic acid protein assay (BCA) (Fisher Scientific, Hampton, NH, USA) and 20 μ g of protein was used for western blot. Blots were then incubated in primary antibody overnight rolling at 4 °C. The following primary antibodies were used: sodium-chloride cotransporter (NCC) (Millipore, Billerica, MA, USA), sodium-potassium-chloride cotransporter (NKCC2) (Millipore, Billerica, MA, USA) [26], NaPi-2a (kind gift of Dr. Jürg Biber [27]), NHE3 (Millipore, Billerica, MA, USA) [28], Na⁺-K⁺-ATPase β 1 (Merck KGaA, Darmstadt, Germany) [29], β -actin (Sigma-Aldrich, St. Louis, MO, USA). Next day, the blots were washed with TBS-T to remove unbound primary antibody and incubated with secondary antibodies for 1 hour at room temperature. Secondary antibodies were as follows: peroxidase conjugated goat anti-rabbit (Sigma Aldrich, Zwijndrecht, The Netherlands); peroxidase conjugated sheep anti-mouse (Jackson ImmunoResearch Laboratories Inc., West Grove, PA, USA). After subsequent washes, the protein was visualized with chemiluminescent reagent (SuperSignal West femto/pico; Thermo Scientific, Waltham, MA, USA). Photos were made with Chemidoc (Bio-Rad Laboratories Inc, Hercules, CA, USA).

Statistical analysis

Parametric data were analyzed using a one-way analysis of variance with Tukey's *post hoc* test to correct for multiple comparisons using GraphPad Prism software 5.0 (GraphPad, CA, USA). One-way ANOVA followed by Scheffe's test was used to examine the differences among groups. All data were shown as mean \pm SEM. Differences were considered to be significant if $P < 0.05$.

Results

Effects of high fat feeding and dapagliflozin on body weight and blood glucose

Mice receiving the high fat diet increased in body weight from day -20 to day 0 more than those receiving normal chow. From day 0 to 18, high fat control mice displayed a further modest increase in body weight, whereas mice treated with dapagliflozin exhibited a significant reduction in body weight. Body weight of lean mice did not differ during the study. High fat control mice displayed increased blood glucose concentrations from day 0 to 18. In contrast, high fat mice treated with dapagliflozin exhibited a marked reduction in blood glucose. Glucose concentrations were unchanged in lean mice. Results are shown in Table 2.

Table 2. Effects of high fat feeding and dapagliflozin on body weight and blood glucose.

Parameter	lean (n=8)		HF+saline (n=8)		HF+DAPA (n=8)	
	d0	d18	d0	d18	d0	d18
Body weight (g)	37.6±5.2	36.0±2.3	45.7±4.2	50.2±4.3 ^a	43.5±5.7	37.6±5.2 ^b
Blood glucose (mM)	5.2±0.9	5.8±0.4	18.5±3.7	22.3±4.1 ^a	17.6±1.7	7.6±2.1 ^b

Lean, lean control mice; HF + saline, high fat diet fed mice receiving saline vehicle; HF + DAPA, high fat diet fed mice receiving dapagliflozin (1mg/kg). d0, day 0, saline vehicle or DAPA were administered; d18, day 18, saline vehicle or DAPA were administered for 18 days; ^aP<0.05 vs. lean, ^bP<0.05 vs. HF + saline.

The effect of dapagliflozin on Na⁺ transporter expression in the proximal tubule

RT-qPCR was performed to analyze the renal expression of *Slc5a1*, *Slc5a2*, *Nhe3*, and *Slc34a1* in the dapagliflozin-treated and control group mice. Gene expression of *Nhe3* and *Slc34a1* was increased significantly by 33% and 34%, respectively, in the dapagliflozin-treated mice compared to high fat control group (Figure 2C and Figure 2D). In contrast, there were no significant differences in the expression of *Slc5a1* and *Slc5a2* between dapagliflozin-treated group and vehicle control group (Figure 2A and Figure 2B). Protein expression level of NaPi-2a and NHE3 was further investigated by Western blot analysis (Figure 2E). The expression of NHE3 and NaPi-2a (*Slc34a1*) was increased by 55% and 139% in dapagliflozin treatment group when compared with saline vehicle diabetic mice (P<0.05) (Figure 2F and Figure 2G).

Figure 2. Effect of dapagliflozin on the expression of the Na^+ transporters in the proximal tubule.

E, Immunoblot analysis of NaPi-2a (~70 kDa), NHE3 (~93 kDa) in mice fed the indicated diet. F and G, Histograms for NaPi-2a, NHE3 Western blots results and normalized for β -actin expression. * $P < 0.05$. Lean, lean control mice; HF + saline, high fat diet fed mice receiving saline vehicle; HF + DAPA, high fat diet fed mice receiving dapagliflozin (1mg/kg).

The effect of dapagliflozin on Na⁺ transporter expression in thick ascending limb of loop of Henle and distal convoluted tubule

In order to study the effect of dapagliflozin on the expression of the Na⁺ transporters in the TAL and DCT, the expression of *Slc12a1*, *Slc12a3*, and *Slc18a1* was analyzed by RT-qPCR. The expression of *Slc12a1* and *Slc12a3* tended to increase by 23% and 17%, respectively, in the dapagliflozin treatment group ($P<0.05$) (Figure 3A and Figure 3B). However, these changes did not reach statistical significance. The expression of *Slc18a1* was shown to decrease by 27% in the dapagliflozin treatment group when compared with saline vehicle control group ($P<0.05$) (Figure 3C). Dapagliflozin treatment did not alter the protein abundance of NCC and NKCC2 when compared with saline vehicle treated diabetic mice (Figure 3D-F)

Figure 3. Effect of dapagliflozin on the expression of the Na⁺ transporters in the loop of Henle and distal convoluted tubule.

A, B, and C, Quantitative RT-PCR analyses for the expression of *Slc12a1*, *Slc12a3*, and *Slc18a1* in the loop of Henle and distal convoluted tubule. D, Immunoblot analysis of NKCC2 (~150 kDa), NCC (~120 kDa) in mice fed the indicated diet. E, Histograms for NCC Western blot results and normalized for β -actin expression. Lean, lean control mice; HF + saline, high fat diet fed mice receiving saline vehicle; HF + DAPA, high fat diet fed mice receiving dapagliflozin (1mg/kg).

The effect of dapagliflozin on the expression of Na⁺ channels in the collecting duct

To further investigate the effect of proximal Na⁺ loss on the Na⁺ transporters in the CD, we tested the expression of the *Scnn1* (*a*, *b* and *g*) by RT-qPCR. Dapagliflozin treatment increased the expression of *Scnn1a* by 29% when compared with vehicle control mice (Figure 4A). In addition, the expression of *Scnn1b* and *Scnn1g* declined significantly by 13% and 26%, respectively, in dapagliflozin-treated group compared to vehicle controls (Figure 4B and Figure 4C).

Figure 4. Effect of dapagliflozin on the expression of the Na⁺ transporters in the collecting duct.

A, B, and C, Quantitative RT-PCR analyses for the expression of *Scnn1a*, *Scnn1b*, and *Scnn1g*, in the collecting duct. *P<0.05. Lean, lean control mice; HF + saline, high fat diet fed mice receiving saline vehicle; HF + DAPA, high fat diet fed mice receiving dapagliflozin (1mg/kg).

The effect of dapagliflozin on the expression of Na⁺-K⁺-ATPase and glucose transporter 2

We also evaluated the effect of dapagliflozin on *Slc2a2* and Na⁺-K⁺-ATPase transporters by RT-qPCR. The expression of *Atp1b1* was significantly increased by 32% in the dapagliflozin-treated mice compared to the vehicle control group (Figure 5B). The expression of *Atp1a1* was not changed in the dapagliflozin-treated group (Figure 5A). Dapagliflozin treatment caused a slight reduction in the expression of *Slc2a2* compared to vehicle control group, but this effect failed to reach statistical significance (Figure 5C). Western blot analysis was further used to investigate the protein expression level of Na⁺-K⁺-ATPase β1. Na⁺-K⁺-ATPase β1 expression was increased by 123% in dapagliflozin treatment group when compared with saline vehicle diabetic mice (Figure 5D-E).

Figure 5. Effect of dapagliflozin on Na⁺-K⁺-ATPase and Slc2a2.

A, B, and C, Quantitative RT-PCR analyses for the expression of *Atp1a1*, *Atp1b1*, and *Slc2a2*. D, Immunoblot analysis of Na⁺-K⁺-ATPase β1 (~50 kDa) in mice fed the indicated diet. Lean, lean control mice; HF + saline, high fat diet fed mice receiving saline vehicle; HF + DAPA, high fat diet fed mice receiving dapagliflozin (1mg/kg).

Discussion

In this study, we demonstrated that inhibition of SGLT2 increased the mRNA expression level of *Nhe3*, *Slc34a1*, and *Scnn1a*. Western blotting results showed that the protein expression level of NHE3 and NaPi-2a was increased in dapagliflozin-treated mice. Moreover, Na⁺-K⁺-ATPase β1 protein expression level was also increased. Our findings demonstrated that proximal inhibition of Na⁺ reabsorption via SGLT2 is compensated by increased expression of local Na⁺ transporters in the PT but not in the TAL, DCT and CD.

The kidneys reabsorb large amounts of filtered glucose to clear urinary glucose, primarily through the SGLT2 in the S1 segment of the PT. Inhibitors of SGLT2 are newly developed anti-diabetic agents and interfere with the pathway of physiological glucose reabsorption in the kidney. In this study, high fat and STZ induction significantly increased blood glucose when compared with lean group mice. In the dapagliflozin treatment group, we found that the blood glucose levels decreased significantly when compared with the vehicle control group. In our study, STZ-induced diabetes decreased SGLT2 expression. María F *et al.* have also demonstrated that STZ decreased SGLT2 expression and activity [30]. In contrast, SGLT2 expression was increased in Akita mice

[31], humans [32] with type 2 diabetes, and alloxan-induced diabetic rats [33]. Indeed, the use of different diabetic models may, therefore, result in different SGLT2 expression. However, despite lower SGLT2 expression in STZ-induced mice, dapagliflozin treatment reduced blood glucose levels. We, therefore, expect that in other studies with higher SGLT2 expression, the observed effects may even be larger. Moreover, dapagliflozin treatment did not change SGLT2 expression in our experiment. The expression of SGLT2 does not necessarily alter upon dapagliflozin treatment. Other studies also found that pharmacological SGLT2 inhibition does not affect the expression of SGLT2 [31, 34]. Given the reduction of blood glucose concentrations in the dapagliflozin-treated group at day 18 when compared with saline vehicle mice, the unchanged SGLT2 expression did not impair the effects of dapagliflozin treatment. Therefore, we do not expect that this has a major impact on our results.

The management of hypertension in diabetes is not without controversy [17]. Hence, the precise level at which anti-hypertensive therapy should be initiated and what the target blood pressure should be, remain difficult issues. Many patients with type 2 diabetes receive multiple drugs to treat both hyperglycemia and hypertension. The new class of SGLT2 inhibitors also induces renal Na^+ wasting and, therefore, will have blood pressure reducing properties. However, some studies report an impressive diuretic effect and consequent reduction in blood pressure, others described modest effects on volume status [17, 35]. It is known that the compensatory capacity of the kidney is immense [36]. Inhibition of Na^+ reabsorption in the PT will turn on compensatory systems in local or more distally located segments to counteract the proximal Na^+ loss.

In this study, dapagliflozin treatment significantly increased the mRNA expression level of *Nhe3*, *Slc34a1* and *Scnn1a*. In line with the mRNA expression level, Western blot results showed that NHE3, NaPi-2a also increased in the dapagliflozin treatment group when compared with saline vehicle mice. Therefore, our results suggest that the inhibition of SGLT2 in the PT can turn on the local Na^+ compensatory systems. Increased reabsorption of Na^+ may result in Na^+ retention and elevate blood pressure in type 2 diabetes [37-39]. Wang *et al.* showed that changed expression of Na^+ transport in renal PT can be compensated by changes in more distal tubule in nephron, by tubuloglomerular feedback and also by glomerular filtration rate adjustments. Nevertheless, extracellular fluid volume and consequently blood pressure can also be affected by the changed expression of Na^+ transport in the PT. Na^+ reabsorption initially happens at the PT apical membrane, therefore resulting in making apical Na^+ transport critical in adjusting the extracellular fluid volume and ultimately blood pressure control [38]. Indeed, in polygenic human essential hypertension, the increase in Na^+ transport occurs at the PT and TAL [40-42] rather than in more distal nephron segments [43]. Unfortunately, there were no plasma and urine electrolytes results in this study. Therefore, further studies are needed to better understand of the compensatory mechanisms of the Na^+ transporters on adjusting blood pressure control.

SGLT2 is located in the S1 segment and accounts for 90% of the glucose reabsorption [44-47]. Na⁺ reabsorption across the cell membrane creates an energy gradient that in turn allows the reabsorption of glucose. On the other side of the cell, Na⁺ is extruded through Na⁺-K⁺-ATPase into the bloodstream [48-50]. Slc2a2 is responsible for transporting glucose into bloodstream [51-53]. In order to evaluate if the increased expression of Na⁺ transporters in the PT influenced the expression of Na⁺-K⁺-ATPase and Slc2a2, we furthermore tested the expression of *Atp1a1*, *Atp1b1*, and *Slc2a2* transporters by RT-qPCR. The results revealed that the expression of *Atp1b1* increased significantly in the dapagliflozin-treated group, however, the expression of *Atp1a1* and *Slc2a2* did not change. Furthermore, Na⁺-K⁺-ATPase β1 protein expression level was also increased in the dapagliflozin-treated group. The increased expression of Na⁺-K⁺-ATPase β1 may facilitate Na⁺ to be transported into the bloodstream, which could lead to salt retention and hypertension. These effects may blunt the potential blood pressure-lowering effects of the SGLT2 inhibitor.

In conclusion, we demonstrated that the SGLT2 inhibitor, dapagliflozin, increased NHE3, NaPi-2a expression in the PT. Furthermore, Na⁺-K⁺-ATPase β1 was also up-regulated which may facilitate the transport of the Na⁺ into the bloodstream. Our findings provide insights that dapagliflozin treatment augments compensatory changes in the renal PT in diabetic mice.

In preparation

Abstract

The incidence of nephrolithiasis has been increasing worldwide in recent decades. Although medical therapies have significantly improved nephrolithiasis treatment, the recurrence rate is still very high after 5 years. Thus, an improved, possibly preventive treatment is needed. Our study aims to develop a novel drug to prevent kidney stone formation, based on our body's calcium (Ca^{2+}) regulation. We developed several Ca^{2+} -binding peptides, analyzed their Ca^{2+} -binding affinity by circular dichroism and tested their safety on renal proximal tubule cells. Results showed a Ca^{2+} -induced change in ellipticity at 220 nm for peptide 4 (Ac-DKNGDGYIDAAE-NH₂). This peptide did not induce cell toxicity and exhibited cellular uptake in Human Kidney-2 (HK-2) cells. To ultimately investigate the biological function of these peptides *in vivo*, we aimed to establish a mouse model of nephrolithiasis. 20 male C57BL/6J mice were given 1% (v/v) ethylene glycol (EG) via drinking water and were administrated either a normal Ca^{2+} diet (0.92% w/w) or a high Ca^{2+} diet (2% w/w) for 28 days. Blood and 24 hours urine were collected on day 1, 7, 14, 21, and 28 for electrolyte analysis. Serum Ca^{2+} concentrations and urinary Ca^{2+} excretions were similar between the two groups, except for day 21 on which serum Ca^{2+} concentration was significantly higher in the high Ca^{2+} diet group. Ca^{2+} crystal deposits were not detected in the kidneys by Von Kossa staining. Together, our study indicated that peptide 4 (Ac-DKNGDGYIDAAE-NH₂) may have the potential to serve as a peptide with low Ca^{2+} -binding affinity in future studies in the kidney stone mouse model. So far, we did not establish such a model as we demonstrated that 1% (v/v) EG administration in drinking water supplied with a high Ca^{2+} diet cannot cause kidney stones in C57BL/6J mice.

Introduction

Nephrolithiasis (kidney stone disease) is a major medical problem with a prevalence ranging from 7-13% in North America, 1-5% in Asia and 5-9% in Europe, and the incidence is predicted to rise in the next decades [1, 2]. This growing trend is generally considered to be due to changes in our lifestyle such as lack of physical activity and poor dietary habits [3]. Kidney stone disease is linked to an increased rate of chronic kidney disease, end-stage renal failure, hypertension, and myocardial infarction [4]. Medical treatment of kidney stones includes dietary management, pharmacological interventions, extracorporeal shock wave lithotripsy, and minor endourological intervention for stone removal [5, 6]. These treatments can result in severe side effects, such as shock wave lithotripsy that may cause acute renal damage [7]. Although medication and minimally invasive surgery have significantly improved acute stone management, the recurrence rate can be up to 14% after 1 year and 35% after 5 years [8]. These data suggest the need for finding a more effective approach to prevent stone recurrence.

Two main predisposing factors for kidney stone formation are hyperoxaluria and hypercalciuria, with the majority of kidney stones being Ca²⁺ oxalate (CaOx) stones [9]. An estimated 40-60% of kidney stone patients have an increased urinary Ca²⁺ excretion [10-12]. Most of these patients have idiopathic hypercalciuria, meaning that the exact underlying mechanism responsible for their hypercalciuria remains unknown [13, 14].

The pathogenesis of nephrolithiasis is a complicated process that is still not entirely elucidated. In general, stone formation includes a cascade of events: urinary supersaturation, nucleation, crystal growth, crystal aggregation, and crystal retention [3, 8]. The pro-urine becomes increasingly concentrated towards the loop of Henle. The osmolality in this segment can increase 10-fold or even higher as a result of the 180-degree turn of the limb of Henle's loop and the minimal reabsorption of water at this segment. This hyperosmolar microenvironment, although crucial for the function of kidney, leads to urinary 'supersaturation' with poorly soluble waste salts such as Ca²⁺ phosphate (CaP) and CaOx, which are the main components for crystal formation [15]. The inability to excrete crystalline material results in the onset of nucleation and is highly appropriate for accumulating Ca²⁺-binding proteins that promote crystal growth and aggregation [3].

In this study, we aimed to develop a Ca²⁺-binding peptide with supersaturation-specific Ca²⁺-buffering capacity that may ultimately be used to investigate the peptide's safety and efficacy by repeated administration in a kidney stone mouse model. Therefore, we used the peptide sequence of the so-called EF-hand protein domain [16]. The structure of an EF-hand is a helix-loop-helix motif linked by a loop of 12 amino acids that are key for Ca²⁺ binding (Figure 2A) [17]. Yap *et al.* compared 90 EF-hand motif structures in 31 EF-hand containing proteins, and found that variations in the amino acids of the Ca²⁺-binding loop can lead to a wide range of Ca²⁺-binding affinities [18]. Based on this knowledge, we synthesized several small EF-hand peptides (around 20-30 residues) and tested their Ca²⁺-

binding affinity. In addition, the present study aimed to establish a kidney stone mouse model. Wildtype (C57BL/6J) mice were treated with 1% (v/v) ethylene glycol (EG) for 28 days via their drinking water while simultaneously placed on either a high- Ca^{2+} (2% w/w) diet or normal Ca^{2+} diet (0.92% w/w) in order to induce Ca^{2+} crystal deposition in the kidney.

Methods and materials

Ethical approval of the study protocol

This study has been approved by the Dutch Central Commission for Animal Experiments (CCD; AVD1030020186805) and the Animal Ethics Board of Radboud University Nijmegen (RU-DEC2018-0030; Nijmegen, The Netherlands).

Chemicals

The EG was provided by Merck Schuchardt OHG and was diluted to 1% (v/v) EG in demi water. Peptides were purchased from EMC Microcollections (Tübingen, Germany), with peptide sequences depicted in Figure 2. All of the peptides in the figure were amino (N)-terminus acetylated (Ac) and carboxy (C)-terminus amidated (NH_2).

Cell culture

HK-2 cells were cultured in Dulbeccos Modified Eagles Medium (DMEM; Gibco, Thermo Fisher Scientific, Waltham, MA, USA) supplemented with Hams-F12 (GE Healthcare, Chicago, USA), HEPES (20 mM) (Gibco, Thermo Fisher Scientific), 1% (v/v) penicillin-streptomycin (Gibco, Thermo Fisher Scientific), 10% (v/v) fetal bovine serum and non-essential amino acids (Lonza Westburg, Arnhem, The Netherlands). The cells were incubated at 37 °C a humidity-controlled incubator with 5% (v/v) CO_2 atmosphere.

Resazurin assay

The resazurin assay (Sigma Aldrich, Zwijndrecht, The Netherlands), staining mitochondrial viability, is used as a measure of cell viability upon exposure of increasing concentrations of peptide to HK-2 cells. At the start of the experiment, 10,000 cells per well were seeded into 96-well plates. After 24 hours, the medium was replaced by a series of peptide concentrations (0-1 mM, dissolved in 50 mM HEPES, pH 8.0 adjusted with NaOH), with peptide diluted in the cell culture medium. Cells were incubated with the peptide for 2, 4, and 24 hours at 37 °C. At the indicated time points, the peptide solution was removed from the cells and 50 μl resazurin (0.1 mg/ml, diluted in medium) was added to the cells and incubated for 4 hours at 37 °C. Subsequently, the quantity of resorufin production (colorimetric change) was measured on a microplate fluorometer (Gibco, Thermo Fisher Scientific) using 540 nm excitation and 620 nm emission wavelength. As controls, three wells were added to each plate with only resazurin (no cells), cells without resazurin, and

100% cell death (1% (v/v) Triton-X-100 (Sigma Aldrich)). All measurements were performed in duplo (1 mM peptide) and triplo (0, 0.01, and 0.1 mM peptide).

Circular dichroism spectroscopy

Circular dichroism (CD) experiments were conducted by using a Jasco J-810 spectropolarimeter (Jasco, Dunmow, United Kingdom) at 20 °C in the wavelength range from 250 to 200 nm. The experiments were done according to Jasco J-810 Spectropolarimeter manual. The measurement was acquired at a scanning speed of 50 nm/min, a bandwidth of 1 nm, a 0.1 nm data pitch and a 2 seconds data integration time were used. Peptide concentration was 250 µM (dissolved in 500 mM HEPES, pH 8.0 adjusted with NaOH) and Ca²⁺ concentrations were 0, 0.5, 1, 5 and 10 mM (dissolved in Milli-Q). Samples were placed in High Precision Cell (Hellma Analytics, College Park, USA) for absorbance measurements.

Proximal tubule cellular peptide uptake

To investigate the potential cellular uptake of the peptide, fluorescence activated cell sorting (FACS) was performed. Cy5-labeled peptides were dissolved in 50 mM HEPES, pH 8.0 NaOH. One day prior to the FACS measurements, 20,000 HK-2 cells per well were seeded in a 96-well plate. After 24 hours, cells were incubated for 15 minutes at 37 °C with different concentration of cy5-labeled peptide (0, 0.01, 0.05, and 0.1 mM, diluted in DMEM) and penetratin-cy5 (0.01 mM) was used as a positive control. Subsequently, cells were washed 3 times with ice cold PBS followed by trypsinization. The cell pellet was resuspended in DMEM and cellular uptake was measured by BD FACSMelody™ cell sorter (Becton Dickinson, Heidelberg, Germany). Cy5-positive cells were excited at a wavelength of 633 nm and emitted at a wavelength of 643–714 nm. The results were analyzed by using FlowJo™ v10.6.1 software (ACEA Biosciences, San Diego, USA).

Animal study

20 healthy 8 weeks-old male C57BL/6J mice were obtained from Charles River Laboratories (Wilmington, MA, USA). All mice had 2 weeks to adjust to the new environment (Animal Research Facility of the Radboud University in Nijmegen, The Netherlands) and their pelleted food (Ssniff Spezialdiäten, Soest, Germany). Next, the animals were placed on a synthetic chow (Ssniff Spezialdiäten) for another 2 weeks. Throughout the whole experiment, the mice were kept in a temperature-controlled room, had free access to water and food, and were exposed to 12 hours dark-light cycles. The mice were randomly grouped in 4 cages (Eurostandard Type II, Amersfoort, The Netherlands) with 5 animals in each cage. During the follow-up period, the animals were kept in their initial cage till the day of their sacrifice.

The cages were randomly divided into two groups: 10 mice were placed on a high Ca²⁺ (HC) diet (2% (w/w) Ca²⁺) while receiving 1% (v/v) EG via their drinking water, and

the other 10 mice continued on the normal Ca^{2+} (NC) (0.92% (w/w) Ca^{2+}) and received 1% (v/v) EG in their water. Both the animal conductor and the researchers were blinded for the experimental diets. The EG-containing water was changed each week to prevent potential breakdown over time.

The mice were placed in individual metabolic cages (Techniplast, Amersfoort, The Netherlands) to collect 24 hour urine on day 1, 7, 14, 21, and 28 (D1, D7, D14, D21, and D28) (Figure 1). To prevent evaporation, 100 μl of mineral oil (Sigma-Aldrich) was added to the urine collecting tubes in the metabolic cage. After each metabolic cage period, two mice from each group were anesthetized with 4% (v/v) isoflurane and sacrificed. Both kidneys were harvested for subsequent analysis. Blood was collected from the retro-orbital sinus bleeding in the sacrificed mice and from the submandibular vein in the mice that were still part of the experiment (Figure 1).

Figure 1. Timeline for the experimental study (days).

At day 0 of the experiment and every following week, the mice were placed in individual metabolic cages. After each metabolic cage period, blood and 24 hours urine were collected from all the mice and two mice from each experimental group were sacrificed and kidneys were harvested, the remaining mice were kept for longer time points. MC, metabolic cage.

Von Kossa staining

The kidney tissues were fixed in 4% (v/v) (neutral) buffered formalin for 24 hours. The kidneys were subsequently put in a descending series of ethanol concentrations (from 100 to 50% (v/v)), cleared in xylene, and embedded in paraffin wax. The paraffin blocks were cut in 5 μm thick sections. Subsequently, 1% (w/v) aqueous silver nitrate solution (Sigma-Aldrich) was added to these samples and they were exposed to 365 nm ultraviolet (UV) light for 30 minutes. The unreacted silver nitrate was removed with 5% (w/v) sodium thiosulfate (Sigma-Aldrich), rinsed in distilled water, and counterstained with 0.1% (w/v) nuclear fast red (Sigma-Aldrich). Subsequently, the slides were dehydrated in an ascending series of ethanol concentrations (from 50-100% (v/v)) and cleared in xylene and mounted with pertex (Histolab, Gothenburg, Sweden). The presence of Ca^{2+} crystal deposits in the kidney tissue was analyzed by using the light microscope Axio Imager M.2 (Carl Zeiss, Oberkochen, Germany) with 10x magnification. Images of the samples were taken using the ZEISS ZEN microscope software (Carl Zeiss).

Serum and urine analysis

Blood was collected on D1, D7, D14, D21, and D28 in microvette tubes (Sarstedt Inc, North Carolina, USA) and was allowed to solidify at room temperature for 30 minutes. Serum was separated from plasma by centrifugation at 1,792 *g* for 5 minutes and an additional 5 minutes at 11,200 *g*. Urinary pH was measured with the SCHOTT pH meter CG 840 (Thermo Fisher Scientific). The serum and urinary magnesium (Mg²⁺) concentrations were measured by using a xylidyl blue colorimetric assay kit in accordance with the manufacturer's protocol (Roche Diagnostics, Woerden, The Netherlands). In short, 5 μ l of standard, precinorm, and diluted samples were added to a 96-well plate. Next, 100 μ l Tris-buffered EGTA pH 11.25 (Roche Diagnostics GmbH, Mannheim, Germany) was added to each well followed by 100 μ l xylidyl blue (Roche Diagnostics GmbH). The results were determined by a VictorX multilabel plate reader (PerkinElmer, Waltham, MA, USA) set to 600 nm. For the serum and urinary Ca²⁺ measurements, a colorimetric assay kit was used in accordance with the manufacturer's protocol (Roche Diagnostics, Woerden, The Netherlands). Serum and urinary Ca²⁺ values were measured by using a VictorX multilabel plate reader (PerkinElmer, Waltham, MA, USA) set to 570 nm. Sodium (Na⁺), potassium (K⁺), chloride (Cl⁻), oxalate, and citrate measurements were performed at the laboratory for diagnostics on an automated system in accordance with the manufacturer's protocol (Abbott Diagnostics, Belgium) at Radboudumc, Nijmegen, The Netherlands.

Statistical analysis

All data were analyzed using Graphpad Prism 7.0 (Graphpad Software, La Jolla, CA, USA), and results were presented as means \pm SEM. Unpaired T-test was used to analyze the difference between the two experimental groups. One-way ANOVA was used to analyze the data within the same group but at the various time points. *P* < 0.05 was considered as statistically significant.

Results

Peptides and Ca²⁺-binding stoichiometry

In order to design our low-affinity Ca²⁺-binding peptides, we used the EF-hand domain as a template. The structure of an EF-hand is comprised of two alpha helices connected by a 12-residue Ca²⁺-binding loop (Figure 2A). This conserved structural motif is present in many protein families and is reported to be important for Ca²⁺-binding [19]. Therefore, several variations in these residues of the Ca²⁺-binding loop were designed and showed in Figure 2B. The Ca²⁺-binding affinity of designed peptides was measured using CD which is able to detect the secondary conformation change of the peptides upon binding of Ca²⁺. A Ca²⁺-induced change in ellipticity at 220 nm was detected upon the addition of Ca²⁺ (from 0 mM to 10 mM) (Figure 2C) for peptide 4, while peptide 1-3 remained unchanged.

Peptide toxicology test

In the CD study, peptide 4 was selected based on its Ca^{2+} -binding affinity. To further investigate the potential toxicity of this peptide on living cells, increasing concentrations of peptide 4 (0-1 mM) were added to HK-2 cells for 2, 4 and 24 hours. A resazurin assay was performed to assess cell viability at these time points. As shown in Figure 3, none of the peptide concentrations resulted in a decreased number of viable HK-2 cells over time, compared to 0 mM peptide, suggesting that peptide 4 is not toxic to the cells. Of note, 1% (v/v) Triton-X100 resulted in significant cell death (Figure 3).

Figure 2. Circular dichroism monitored Ca^{2+} and peptide binding.

B, The sequence for designed peptides and consensus EF-hand motif. Negative charged amino acids that bind with Ca^{2+} were marked in dark green color. C-G, Circular dichroism detection for indicated peptides to assess conformational changes upon Ca^{2+} -binding under different concentrations of Ca^{2+} . H, zoom in image from figure G. The data is an average of three measurements in one experiment, with the experiment performed once. CD, Circular dichroism.

Cellular peptide uptake in HK2 cells

In order to detect whether peptide 4 can be taken up by the proximal tubule cells, HK2 proximal tubular cells were incubated with increasing concentrations of Cy5-labelled peptide 4 and Cy5-labelled penetratin as positive control for 15 minutes at 37 °C. FACS results showed that the Cy5 signal increased with a higher concentration of peptide 4. Yet, the Cy5-labelled signal of 0.01 mM penetratin was 9.5 and 1.5 times higher than the Cy5-labelled signal of 0.01 mM and 0.1 mM peptide, respectively (Figure 4).

Figure 3. Resazurin assay for testing the cell viability by adding peptide 4 in HK-2 cells.

Increasing concentrations (0-1 mM) of peptide 4 were added to HK-2 cells and incubated for 2, 4, and 24 hours. Resorufin production was measured after 4 hours of incubation with resazurin. The red line represents the condition in which all the HK-2 cells are dead. This experiment was performed twice in triplicate.

Metabolic parameters in mice

In order to investigate crystal deposition in mouse kidney, C57BL/6J mice were placed on a high Ca²⁺ (HC) or normal Ca²⁺ (NC) diet while receiving 1% (v/v) EG via their drinking water for 28 days. Body weight, food intake, water intake were measured and were not statistically different between the groups throughout the whole experiment (Table 1). Of note, the water intake in the group of mice treated with the NC diet was significantly higher on D14 and D21 compared to D1. Blood and 24 hours urine were collected after each metabolic cage period. In line with an increased water intake, urine volume in the NC group was higher on D21 compared to D1, D7, and D14. The 24 hours urine volume in the HC diet group was also significantly increased on D21 compared to D1 (Table 1).

Figure 4. Peptide 4 exhibited cellular uptake in HK-2 cells.

Increasing concentrations of peptide 4 (0–0.1 mM) and penetratin as positive control were added to HK-2 cells for 15 minutes. After cell lysis, cellular uptake of the cy5-labeled peptides was counted by FACS with Cy5 fluorescence. This experiment was performed twice in triplicate.

Serum and urinary electrolyte handling in mice

To investigate the effect of EG and the diets on electrolyte handling, serum, and 24 hours urine electrolyte levels were analyzed. Serum Ca^{2+} concentrations and urinary Ca^{2+} excretion were similar between NC and HC groups, except on D21 where the serum Ca^{2+} concentration was significantly higher in the HC group (2.6 ± 0.1 mmol/L) compared to the NC group (2.3 ± 0.1 mmol/L) (Table 2-3). Other serum values (Na^+ , K^+ , Cl^- , and Mg^{2+}) did not differ significantly between HC and NC groups (Table 3). The urinary values were also similar between groups, except for two conditions. The urinary Na^+ excretion on D7 increased by 14% in the HC group compared to the NC group. The urinary Mg^{2+} excretion on D14 decreased by 19% in the NC group compared to the HC group (Table 2).

However, we observed changes in urinary electrolyte excretion within either group over the time course of the experiment. Within the NC groups, the urinary Na^+ , Cl^- and K^+ concentrations were significantly higher on D21 compared to D1, D7, and D14 (Table 2). While urinary Ca^{2+} levels on day 21 in the NC group were higher compared to all other days (D1, D7, D14), urinary Ca^{2+} excretion in the HC group was only higher on D21 compared to D1. Moreover, there was no significant difference in urinary Mg^{2+} levels over time in the NC group and higher urinary Mg^{2+} levels were detected on D21 in the HC group compared to D1 and D14 (Table 2).

Table 1. Metabolic parameters of mice under normal Ca²⁺ (NC) and high Ca²⁺ (HC) diet.

Serum was collected on day 1 (D1), day 7 (D7), day 14 (D14), day 21 (D21) and day 28 (D28) after placing the mice in metabolic cages for 24 hours. Serum Na⁺, K⁺, and Cl⁻ levels were measured. n=2 for each group on D1, D7, D14, D21, and D28. Serum Ca²⁺ and Mg²⁺ levels were measured. n=10 for each group on D1, n=8 for each group on D7, n=6 for each group on D14, n=4 for each group on D21, and n=2 for each group on D28. Numbers represent the mean ± SEM. a, compared to the normal Ca²⁺ group at the same time point. NC, normal Ca²⁺; HC, high Ca²⁺.

Measurement of urinary citrate and urinary oxalate excretion and the urinary pH in mice

Urinary citrate and oxalate levels were measured at the beginning and end of the experimental time frame. On day 28, urinary citrate excretion was increased by 37% in the HC group compared to the NC group (Figure 5A). In the HC group, the oxalate excretion was nearly 6.3 folds and 5.9 folds higher than mice fed the NC diet at D1 and D28, respectively (Figure 5B). The urinary pH was similar between the NC and HC groups (Figure 5C).

Figure 5. Urinary citrate and oxalate excretion and pH of mice under normal Ca^{2+} (NC) and high Ca^{2+} (HC) diet.

(A-C) Urinary citrate (A) and oxalate (B) excretion and pH (C) were investigated after placing the mice in metabolic cages for 24 hours. $n=2$ for each group for urinary citrate and oxalate measurement. For urinary pH measurement, $n=10$ for each group on D1, $n=8$ for each group on D7, $n=6$ for each group on D14, $n=4$ for each group on D21 and $n=2$ for each group on D28. D represents day.

Von kossa staining for Ca^{2+} deposit in mice kidney

In order to assess whether 1% (v/v) EG was able to induce crystal deposition in the kidneys of the mice, Von kossa staining was conducted on kidney tissue. The trachea from *Klotho* knockout mice were used as positive control since they develop CaP precipitates [21, 22]. Von Kossa staining results showed that Ca^{2+} deposits were not observed by using 1% (v/v) EG administration in drinking water combined with a HC diet for 28 days (Figure 6).

Figure 6. Von Kossa staining for Ca²⁺ deposits in mice kidney.

Representative staining of kidney tissue from each experimental group (normal Ca²⁺ (NC) and high Ca²⁺ (HC) diets) on day 1 (D1), day 7 (D7), day 14 (D14), day 21 (D21) and day 28 (D28). Trachea from *Klotho* knockout mice was used as a positive control. n=2 for each group. Size bar represents 25 μ m.

Discussion

In this study, several shortened EF-hand peptides with altered sequences were analyzed for their Ca²⁺-binding capacity. The aim was to identify a peptide with low binding affinity for Ca²⁺ (2-5 mM range). Our preliminary results suggest that peptide 4 (Ac-DKNGDGYIDAAE-NH₂) has the potential to serve as such a peptide. Moreover, this peptide did not induce cellular toxicity but did show mild cellular uptake in HK-2 cells. To ultimately evaluate the efficacy of this peptide *in vivo*, we aimed to generate a nephrolithiasis mouse model by administering 1% (v/v) EG via drinking water in combination with either a normal or a high Ca²⁺ diet. However, no Ca²⁺ crystal deposits were observed in the kidney tissues of mice on either diet.

Previously, Reid *et al.* developed a Ca²⁺-binding peptide (α -helix-DKNGDGYISAAE- α -helix) with a Ca²⁺-binding affinity in the micromolar range (K_d =59 μ M) [23]. We used the Ca²⁺-binding loop (DKNGDGYISAAE) as template and changed the amino acid residue at position 9 from S to D. The CD spectra of the peptide showed a Ca²⁺-induced change in ellipticity at 220 nm upon the incremental addition of Ca²⁺ in the millimolar range, which suggested that the Ca²⁺-binding affinity of this peptide is decreased compared to the study by Reid *et al.* With the alteration from S to D, our peptide had 3 acidic side chains. In contrast to what we found, the acid pair hypothesis suggests that more acidic

side chains (within four) in the loop lead to a higher Ca^{2+} -binding affinity [24]. In addition, D is negatively charged and exhibits increased binding affinity to Ca^{2+} compared to S in the study of Reid *et al* [23]. We suspect that the decreased binding affinity to Ca^{2+} in our peptide is due to the removal of the flanking α -helices, compared to the Ca^{2+} -binding peptide developed by Reid *et al*. This is in line with the idea proposed by Lakowski *et al*. that the absence of the flanking helix of the EF-hand loop reduces Ca^{2+} -binding affinity [25].

Preliminary results from our study demonstrated that this peptide is not toxic. The presence of residues like C, H, N, and P was shown to be higher in toxic peptides compared to non-toxic peptides [26]. In agreement with their findings, the peptide we designed had only one N residue. Moreover, FACS results showed that the amount of peptide cellular uptake increased at higher concentrations, but remained lower than the uptake of the cell-penetrating peptide penetratin. This indicated that the peptide (Ac-DKNGDGYIDAAE-NH₂) exhibited cellular uptake, which might be caused by the high concentrations of peptide added to the cells. In general, receptor-mediated endocytosis plays a crucial role in the reabsorption of low molecular weight proteins in the proximal tubule [27]. Megalin, which is expressed in the apical side of the PT, interacts with its associated protein such as cubilin, and contributes significantly in the receptor-mediated endocytosis process [28-30]. Therefore, megalin and cubilin may also play a role in the reabsorption of the peptide we designed. Although these peptide *in vitro* experiments are very encouraging, more repeats still need to be performed due to some of them were conducted less than three times.

In contrast to our *in vivo* study, other studies have successfully induced nephrolithiasis in mice and rats by administrating EG. A study in rats showed that intraperitoneal injection with EG led to the development of CaOx crystal deposits after 2-4 weeks [31]. This suggests that the absence of crystal deposition in the renal tissue of the mice in our study may be due to species differences. Other studies have successfully used Swiss albino mice to induce crystal formation by administering 0.75% (v/v) EG via the drinking water for 28 days [32]. The difference in susceptibility to stone formation between C57BL/6J mice and Swiss albino mice may lie in the genetic background of these animals [32]. Though, C57BL/6J mice have been used previously to study nephrolithiasis, with variation in genetically modified models, the agents that were used, and the method of administering. In 2007, Okada *et al*. successfully detected kidney stones in male C57BL/6J (wildtype) mice by intraabdominal glyoxylate injection [33]. Here, they found that the expression of osteopontin (OPN), which is an important kidney stone-related protein, was significantly increased [33]. OPN expression was not measured in our study. In addition, Jiang *et al*. demonstrated that mice lacking solute carrier family 26 member 6 (*Slc26a6*), which is a Cl^- -oxalate exchanger [34], are more prone to develop CaOx nephrolithiasis compared to wildtype mice [35]. In their later study, they demonstrated that only the *Slc26a6* knockout mice with hypercalciuria develop crystal deposits in the kidney, which

suggests that hypercalciuria plays a very important role in forming kidney stones [34]. This is substantiated by a study by Khan *et al.* concluding that hyperoxaluria alone is not enough to induce CaOx crystal deposits, both hypercalciuria and hyperoxaluria are required in mice [36]. Importantly, hypercalciuria was not detected in the mice of our study, which could explain the fact that we did not observe crystal deposits.

The fact that a HC diet did not induce changes in serum and/or urinary Ca²⁺ levels might be due to the compensatory loss in the gastrointestinal tract. Under high Ca²⁺ intake conditions, Ca²⁺ is passively absorbed by the paracellular process in the jejunum and ileum leading to lower fractional absorption of Ca²⁺ and loss of Ca²⁺ in the feces [37]. Thus, it is necessary to measure the Ca²⁺ levels in the feces in order to elucidate whether the normal serum Ca²⁺ levels are caused by fecal Ca²⁺ loss in the mice treated with HC diets.

And finally, it is important to note a few limitations of this pilot study. While EG is not expected to affect serum and urinary parameters, a control group (without EG) would be optimal. Moreover, we sacrificed 2 animals per time point, leaving only 2 mice per group at day 28. Therefore, it is not possible to draw any significant conclusions on urinary markers after day 21. Also, this resulted in more variability of the measured electrolyte levels, limiting statistical testing. On this note, the significantly higher water intake in the NC diet treated mice on D14 and D21 was due to one extreme value (mice) that we could not omit because of the small sample size.

Taken together, our *in vitro* study revealed that peptide 4 (Ac-DKNGDGYIDAAE-NH₂) can be potentially used for single or repeated injection in a kidney stone mouse model. Our *in vivo* study showed that the EG administration in drinking water supplied with a HC diet is not sufficient for nephrolithiasis induction in C57BL/6J mice. For future studies, it might be interesting to use Swiss albino mice or rats to induce kidney stone disease. When the kidney stone model is set up, we can investigate if the peptide can be served as the first step towards the development of a new therapeutic intervention for kidney stone recurrence.

Abstract

Magnesium (Mg^{2+}) homeostasis is maintained by intestinal absorption and renal excretion. Genome wide association studies (GWAS) investigated genetic loci associated with urinary Mg^{2+} excretion in 9099 individuals and identified ADP-ribosylation factor-like GTPase 15 (*ARL15*). Moreover, it was shown that *ARL15* can regulate Mg^{2+} reabsorption by regulating the channel activity of TRPM6 in the kidney, but the function of *ARL15* in the kidney is still unknown. The objective of this study was to further characterize *ARL15* and its role in Mg^{2+} homeostasis in the kidney by using *Arl15* heterozygous (*Arl15*^{+/-}) mice. The *ARL15* gene has 795 bp encoding a protein of 265 amino acids. Iterative Threading ASSEmbly Refinement (I-TASSER) prediction showed that the secondary structure of *ARL15* consists of 8 alpha-helices, 7 beta-strands and belongs to the small GTPase superfamily. Furthermore, Mg^{2+} is predicted to bind to *ARL15*. Tissue distribution indicated that *ARL15* is ubiquitously expressed in mouse tissue, with the highest abundance in the lung, inguinal fat, epididymal fat, spleen, testes, and kidney. Differences in serum Mg^{2+} concentration and 24 hours urinary Mg^{2+} excretion were not detected between *Arl15* wildtype (*Arl15*^{+/+}) and *Arl15*^{+/-} mice on the high fat and low fat diets. Furthermore, on the low fat diet, water intake of male *Arl15*^{+/-} mice was significantly increased by 60% compared to male *Arl15*^{+/+} mice. On the high fat diet, body weight of female *Arl15*^{+/-} mice significantly decreased by 12% compared to female *Arl15*^{+/+} mice. However, food intake and 24 hours urine volume did not significantly differ between the groups on the high fat and low fat diets. Quantitative real-time PCR analysis showed that the mRNA expression levels of Mg^{2+} -related genes, metabolism-related genes, and membrane trafficking-related genes are not affected in the kidney of *Arl15*^{+/-} mice. Thus, our results suggest that *ARL15* does not play a role in the regulation of renal electrolyte transport.

Introduction

Magnesium (Mg^{2+}) plays an important role in the synthesis, folding, and stability of biomolecules and it works as a cofactor for various enzymatic reactions [1]. Mg^{2+} also plays an essential role in stabilization of the cell membrane, cardiac excitability, regulation of blood pressure, glucose-insulin metabolism, and muscle contraction [2, 3]. An adult human body contains approximately 22-26 grams (g) of Mg^{2+} [4]. Only 1% of the total Mg^{2+} in the body is found in the extracellular space, which is primarily in blood [1].

The kidney plays a key role in the regulation of blood Mg^{2+} concentration. Around 95-99% of the filtered Mg^{2+} is reabsorbed in the proximal tubule (PT), the thick ascending limb (TAL), and the distal convoluted tubule (DCT) of the kidney [5]. Although the DCT reabsorbs only 5-10% of the filtered Mg^{2+} [6], it is the last segment to determine the final Mg^{2+} concentration in urine since no Mg^{2+} reabsorption takes place beyond this segment [5, 6]. Transient receptor potential cation channel subfamily M member 6 (TRPM6) is the gatekeeper of transcellular Mg^{2+} reabsorption in the DCT [6, 7]. Its importance in Mg^{2+} homeostasis is highlighted by the fact that mutations in the *TRPM6* gene lead to hypomagnesemia with secondary hypocalcemia (HSH) [8].

Recently, a GWAS identified ADP-ribosylation factor-like protein 15 (ARL15) to be associated with urinary Mg^{2+} wasting [9]. ARL15 belongs to the ADP-ribosylation factor (ARF) family [9]. Immunohistochemical studies demonstrated its localization in the TAL and DCT of the kidney [9], but the function of this protein has not yet been clarified. A recent study proposed that ARL15 may be involved in the regulation of intracellular vesicle trafficking [9]. In line with this, Corre *et al.* found that TRPM6 channel activity is significantly increased in the presence of ARL15, and knockdown of *Arl15* in zebrafish resulted in urinary Mg^{2+} wasting [9]. Thus, this set of experiments suggests that ARL15 is a key protein in maintaining Mg^{2+} homeostasis.

Additional GWAS showed a strong association between *ARL15* locus variants and several metabolic and cardiovascular traits including risk of diabetes mellitus type 2, elevated fasting insulin concentration, hemoglobin A1C (HbA1c) levels and pancreatic beta cell proliferation [8, 10-14]. Indeed, Rocha *et al.* demonstrated that knockdown of *Arl15* significantly impaired the adipogenesis and adiponectin secretion of 3T3-L1 cells [11].

The aim of this study was, therefore, to characterize the role of ARL15 in renal Mg^{2+} handling and metabolic traits. For this purpose, *Arl15* heterozygous knockout (*Arl15*^{+/-}) mice were analyzed for electrolyte homeostasis and renal abnormalities. Furthermore, by challenging the mice with high fat diets, the mRNA expression of Mg^{2+} -related, metabolism-related and membrane trafficking related-genes was investigated by quantitative real-time-PCR (RT-qPCR).

Methods and materials

Ethical approval of the study protocol

All mice models used in this experiment were approved by animal ethics board of Radboud University (Nijmegen, The Netherlands) and the MRC Harwell Institute of Animal Welfare and Ethical Review Committee. All procedures were performed in accordance with the Home Office license 30/3146 and 30/3070 under the Animal (Scientific Procedures) Act 1986 which is issued by the Medical Research Council.

Mice were kept under a 12:12 hour light/dark cycle (lights on 7 am and off 7 pm), at a temperature of $21\pm 2^{\circ}\text{C}$ and a humidity of $55\pm 10\%$ conditions. Mice had free access to water (9–13 ppm chlorine) and were maintained *ad libitum* on either a high fat diet (D12492, Research Diets, New Brunswick, NJ, U.S.A.) or low fat diet (D12450J, Research Diets, New Brunswick, NJ, U.S.A.) for 24 weeks from weaning.

Expression profiling and quantitative real time PCR

Three 12-weeks old wildtype C57BL/6 mice were sacrificed. Brain, retina, aorta, lung, heart, stomach, caecum, duodenum, jejunum, ileum, colon-ascend, colon-descend, rectum, brown fat, inguinal fat, epididymal fat, thigh muscle, spleen, adrenal gland, kidney, and testes were collected. 10 *Ar15*^{+/-} mice and *Ar15*^{+/+} littermate controls with C57BL/6NTac background were sacrificed in the end of experiment. Total RNA was extracted from above described tissues with Trizol (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's protocol. Subsequently, RNA samples were subjected to DNase (Invitrogen, Breda, The Netherlands) treatment to prevent genomic DNA contamination and the reverse transcriptase reaction was performed for 1 hour at 37°C to synthesize cDNA. mRNA levels of the target genes were determined with a CFX96TM Real-Time PCR Detection System (Bio-Rad Laboratories, Hercules, CA) using iQTM SYBR Green Supermix (Bio-Rad) detection of single PCR product accumulation. All RT-qPCR experiments were executed in triplicate. Gene expression levels were normalized to the expression levels of the standard reference gene glyceraldehyde 3-phosphate dehydrogenase (*Gapdh*). Relative mRNA expression was analyzed using the Livak method ($2^{-\Delta\Delta C_t}$). All primers were purchased from Biolegio BV (Nijmegen, Netherlands). Primer sequences are shown in Table 1.

Bioinformatics analysis

To further understand ARL15 protein function, bioinformatics analysis was performed. Gene structure analysis, homologous alignment, signal peptide and protein conserved domain prediction was performed using the following sources: <https://blast.ncbi.nlm.nih.gov/Blast.cgi>, and <https://zhanglab.ccmb.med.umich.edu/I-TASSER/>.

Serum and urinary Mg^{2+} measurements

Serum and urinary total Mg^{2+} concentrations were measured by a colorimetric xylidyl-II blue assay kit (Roche Diagnostics, Woerden, The Netherlands), according to the protocol provided by the manufacturer. Urine volume was measured in order to calculate 24 hours Mg^{2+} excretion.

Immunohistochemistry

Adrenal gland, kidney, testes, and fat tissue were fixed in 4% (w/v) paraformaldehyde for 24 hours, and embedded in paraffin. Subsequently, 5 μ m sections were cut and serial 5 μ m paraffin-embedded tissue sections were deparaffinized and rehydrated. Endogenous peroxidase activity was inhibited by incubating the sections in 3.0% (v/v) hydrogen peroxide (H_2O_2) (Avantor, Arnhem, The Netherlands). After blocking the sections with 20% (v/v) goat serum in phosphate-buffered saline (PBS), the sections were incubated overnight at 4°C with ARL15 antibody (Abcam, Cambridge, The UK). Then, the sections were incubated with the swine anti-rabbit secondary antibody (Abcam, Cambridge, UK). Sections were imaged by using the light microscope Axio Imager M.2 (Carl Zeiss, Oberkochen, Germany). Blinded analysis of positive immunostained sections were performed using Image Pro Plus (Media Cybernetics, Warrendale, Pennsylvania).

Statistical analysis

All data were analyzed using Graphpad Prism 7.0 (Graphpad Software, La Jolla, CA, USA), and results were presented as means \pm SEM. Results are statistically analyzed by performing a two-way ANOVA followed by Tukey as post-test. $P < 0.05$ was considered as statistically significant.

Results

Identification of ARL15 gene and protein comparison

ARL15 has an open reading frame of 795 bp encoding a protein of 265 amino acids. The protein sequence is highly conserved and comparison analysis showed that human and mouse ARL15 share 74% similarity in amino acid sequence. In order to elucidate the function of ARL15, secondary protein analysis was performed. Structure prediction indicated that ARL15 consists of 8 alpha-helices and 7 beta-strands. I-TASSER prediction

for the tertiary structure of ARL15 showed that it belongs to the small GTPase superfamily (Figure 1A). Interestingly, Mg^{2+} is shown to interact with the surrounding T107 and T124 residues of ARL15 (Figure 1B and C).

Analysis of *Arl15* expression in different mouse tissues

To investigate the tissue distribution of *Arl15*, RNA was isolated from various tissues of adult mice and gene expression was analyzed by RT-qPCR. *Arl15* mRNA was highly expressed in lung, inguinal fat, epididymal fat, spleen, testes, and kidney, followed by the retina, stomach, duodenum, ileum (Figure 2A). It was weakly detectable in brain, aorta, liver, heart, caecum, jejunum, colon, rectum, adrenal gland, brown fat, and thigh-muscle (Figure 2A). Protein expression of ARL15 in adrenal gland, brown fat, kidney, and testes in adult mice was further investigated by immunohistochemistry. ARL15 was highly expressed in the cortex and medulla of the adrenal gland (Figure 2B, panel a). In the kidney, ARL15 was present in the TAL and DCT (Figure 2B, panel b). There was a robust expression in the adipocytes in inguinal fat (Figure 2B, panel c). Moreover, ARL15 was highly expressed in the spermatoblast and interstitial cells in testes (Figure 2A, panel d).

Normal metabolic parameters in *Arl15*^{+/-} mice

The function of ARL15 *in vivo* was further investigated in *Arl15*^{+/+}, *Arl15*^{+/-} and *Arl15*^{-/-} mice (kindly provided by Dr. Roger Cox). The importance of ARL15 for metabolism was indicated by the fact that *Arl15*^{-/-} mice, generated via CRISPR/Cas9 germline knockout, died after birth (unpublished data from Roger Cox's group). The *Arl15*^{+/+} and *Arl15*^{+/-} mice are viable (unpublished data from Roger Cox's group) and were subjected to low and high fat diets for 24 weeks after weaning. At the end of the experiments, mice were placed in metabolic cages for 24 hours to collect blood and 24 hours urine for further analysis.

Blue arrow in panel a represents cortex of the adrenal gland, black arrow in panel a represents medulla of the adrenal gland, black arrow in panel b represents distal convoluted tubule of the kidney, blue arrow in panel b represents thick ascending loop of Henle of the kidney, black arrow in panel c represents adipocytes, black arrow in panel d represents testis spermatoblast, blue arrow in panel d represents interstitial cells. Size bar represents 25 μ m.

On the low fat diet, water intake of male *Arl15*^{+/-} mice was significantly increased by 60% compared to male *Arl15*^{+/+} mice (Table 2). On the high fat diet, body weight of female *Arl15*^{+/-} mice was significantly decreased by 12% compared to female *Arl15*^{+/+} mice (Table 2). However, food intake and urine volume did not significantly differ between the groups on the respective diets (Table 2).

Table 2. Metabolic parameters of *Arl15*^{+/-} Mice

Male	Low fat diet		High fat diet	
	<i>Arl15</i> ^{+/+}	<i>Arl15</i> ^{+/-}	<i>Arl15</i> ^{+/+}	<i>Arl15</i> ^{+/-}
Weight (g)	35.2 ± 1.5	33.3 ± 1.1	45.4 ± 0.6	43.6 ± 1.7
Food intake (g)	4.7 ± 0.5	4.4 ± 0.5	1.5 ± 0.2	1.2 ± 0.2
Water intake (mL)	2.2 ± 0.3	3.6 ± 0.5 ^a	1.9 ± 0.2	1.7 ± 0.2
Urine volume (mL)	1.2 ± 0.2	1.2 ± 0.1	0.9 ± 0.1	1.0 ± 0.1

Female	Low fat diet		High fat diet	
	<i>Arl15</i> ^{+/+}	<i>Arl15</i> ^{+/-}	<i>Arl15</i> ^{+/+}	<i>Arl15</i> ^{+/-}
Weight (g)	26.6 ± 0.8	27.8 ± 0.8	46.6 ± 1.5	41.8 ± 1.4 ^b

Arl15^{+/+} and *Arl15*^{+/-} mice were kept on low fat and high fat diets for 24-weeks. During the last 24 hours, the mice were placed in metabolic cages to collect blood and 24 hours urine. Numbers represent mean ± SEM. a represents a significant difference compared to *ARL15*^{+/+} mice on low fat diet; b indicates a significant difference compared to *ARL15*^{+/+} mice on high fat diet. +/+, *Arl15* wildtype mice, +/-, *Arl15* heterozygous mice.

Effects of low and high fat diets on Mg²⁺ handling in *Arl15*^{+/+} and *Arl15*^{+/-} mice

To investigate the role of ARL15 in Mg²⁺ handling, serum Mg²⁺ concentration and 24 hours urinary Mg²⁺ excretion were measured in male and female *Arl15*^{+/+} and *Arl15*^{+/-} mice. Mg²⁺ excretion was nearly 3 folds lower in female *Arl15*^{+/-} mice on high fat diets compared to female *Arl15*^{+/+} mice fed low fat diets (Figure 3D). However, serum Mg²⁺ concentration and 24 hours urinary Mg²⁺ excretion did not alter significantly between the other groups (Figure 3A-D).

The expression of Mg²⁺-related genes in the kidney of *Arl15*^{+/+} and *Arl15*^{+/-} mice

To further study the role of ARL15 in renal Mg²⁺ handling, the expression of Mg²⁺-related genes in the kidney of *Arl15*^{+/+} and *Arl15*^{+/-} mice fed low fat or high fat diets were evaluated by RT-qPCR. While the expression of *Cldn16* did not change between male *Arl15*^{+/-} mice on high fat and low fat diets (Figure 4A), *Cldn16* expression in female *Arl15*^{+/+} mice treated with high fat diets was significantly decreased compared to female *Arl15*^{+/+} mice fed

with low fat diets (Figure 4G). *Fxyd2* expression in both male and female *Arl15*^{+/-} mice on high fat diets was significantly higher compared to the mice fed low fat diets (Figure 4B, H). Expression of *Cnnm2*, *Slc41a1*, *Slc41a3*, and *Trpm6* was not affected between the conditions (Figure 4C- F, I-L).

Figure 3. *Arl15*^{+/-} mice exhibit normal serum Mg^{2+} concentrations and urinary Mg^{2+} excretions.

A, B, Serum Mg^{2+} concentrations of male (A) and female (B) *Arl15*^{+/+} and *Arl15*^{+/-} mice fed with either low fat or high fat diets. C, D, 24 hours urinary Mg^{2+} excretion of male (C) and female (D) *Arl15*^{+/+} and *Arl15*^{+/-} mice treated with either low fat or high fat diets. Values were presented as single data points with means \pm SEM. +/+, *Arl15* wildtype mice, +/-, *Arl15* heterozygous mice, LF, low fat diets, HF, high fat diets.

The expression of metabolism-related genes in the kidney of *Arl15*^{+/+} and *Arl15*^{+/-} mice

GWAS showed that variants of *ARL15* were associated with serum adiponectin levels, fasting insulin levels, and triglyceride concentrations [12, 15]. Therefore, RT-qPCR was commenced to analyze the expression of metabolism-related genes in the kidney of *Arl15*^{+/+} and *Arl15*^{+/-} mice fed with low fat and high fat diets.

Figure 4. Mg^{2+} -related gene expression did not alter between *Arl15*^{+/+} and *Arl15*^{+/-} mice.

The mRNA expression levels of *Cldn16*, *Cnnm2*, *Fxyd2*, *Slc41a1*, *Slc41a3*, and *Trpm6* in the kidney of male (A-F) and female (G-L) *Arl15*^{+/+} and *Arl15*^{+/-} mice fed with either low fat (LF) or high fat (HF) diets were measured by RT-qPCR. Results were normalized to *Gapdh* expression (reference gene). * P < 0.05 indicates statistical significance. *Cldn16*, Claudin-16; *Cnnm2*, Cyclin and CBS domain divalent metal cation transport mediator 2; *Fxyd2*, FXYD domain containing ion transport regulator 2; *Slc41a1*, Solute carrier family 41 member 1; *Slc41a3*, Solute carrier family 41 member 3; *Trpm6*, Transient receptor potential cation channel subfamily M member 6; *Gapdh*, Glyceraldehyde 3-phosphate dehydrogenase. +/+, *Arl15* wildtype mice, +/-, *Arl15* heterozygous mice.

Figure 5. Metabolism-related gene expression did not change between *Arl15*^{+/+} and *Arl15*^{+/-} mice.

The mRNA expression levels of *Adipor1*, *Adipor2*, *Adb3*, *Cpt1*, *Cpt2*, *Slc5a1*, *Slc5a2*, *Pepck1*, and *Plin1* in the kidney of male (A-I) and female (J-R) *Arl15*^{+/+} and *Arl15*^{+/-} mice fed with low fat or high fat diets were measured by RT-qPCR. Results were normalized to *Gapdh* expression (reference gene). Data represent means \pm SEM and are expressed as fold difference compared to *Arl15*^{+/+} mice on low fat diets. * $P < 0.05$ indicates a statistically significance. +/+, *Arl15* wildtype mice, +/-, *Arl15* heterozygous mice, LF, low fat diet, HF, high fat diet. *Adipor1*, Adiponectin receptor 1; *Adipor2*, Adiponectin receptor 2; *Adb3*, Beta-3 adrenergic receptor; *Cpt1*, Carnitine palmitoyltransferase 1; *Cpt2*, Carnitine palmitoyltransferase 2; *Fabp1*, Fatty acid-binding protein 1; *Slc5a1*, Solute carrier family 5 member 1; *Slc5a2*, Solute carrier family 5 member 2; *Pepck*, Phosphoenolpyruvate carboxykinase; *Plin1*, Perilipin 1.

Gene expression of *Adipor1*, *Adipor2*, *Adrb3*, *Cpt1*, *Cpt2*, *Slc5a1*, *Slc5a2*, *Pepck* and *Plin1* were analyzed. Gene expression of *Adipor1* was significantly lower in female *Arl15^{+/-}* mice on high fat diets compared to the mice treated with low fat diets (Figure 5J). Gene expression of *Adipor1* was not affected in male *Arl15^{+/-}* mice on either diet (Figure 5A). The expression of *Slc5a2* in female *Arl15^{+/-}* or *Arl15^{-/-}* mice fed with low fat diets were lower than female *Arl15^{+/-}* or *Arl15^{-/-}* mice fed with high fat diets respectively (Figure 5P). However, the expression of *Slc5a2* in male *Arl15^{+/-}* or *Arl15^{-/-}* mice was not changed with either diet (Figure 5G). The expression of other genes, such as *Adipor2*, *Ardb3*, *Cpt1*, *Cpt2*, *Slc5a1*, *Pepck1* and *Plin1* were not affected in male or female *Arl15^{+/-}* or *Arl15^{-/-}* mice exposed to the high fat or low fat diets (Figure 5B-F, H, I, K-N, Q, and R).

Expression of membrane trafficking-related genes in the kidney of *Arl15^{+/-}* and *Arl15^{-/-}* mice

ARL15 was predicted to be a small GTPase and protein-protein interaction prediction showed that ARL15 interacts with vesicular trafficking genes [9]. In order to examine whether reduced ARL15 expression was compensated by other small GTPase involved in intracellular vesicle trafficking, the expression of *Arf1*, *Arfgef-1*, *Arfgef-2*, and *Arf6* was measured by RT-qPCR in the kidney of *Arl15^{+/-}* and *Arl15^{-/-}* mice fed with low fat and high fat diets. However, the results indicated that expression of *Arf1*, *Arfgef-1*, *Arfgef-2*, and *Arf6* in male or female *Arl15^{+/-}* or *Arl15^{-/-}* mice treated with high fat and low fat diets did not change significantly (Figure 6A-H).

Discussion

This study demonstrated that *Arl15^{+/-}* mice have a normal phenotype, and exhibit no changes in serum Mg^{2+} concentration or urinary Mg^{2+} excretion. Furthermore, there was no altered expression of Mg^{2+} -related, metabolism-related, and membrane trafficking-related genes in *Arl15^{+/-}* mice compared to *Arl15^{+/-}* mice. Taken together, these findings showed that partial loss of ARL15 does not impair renal Mg^{2+} handling and metabolism. Other models may be required to study the role of ARL15 in the kidney.

ARL15 was predicted to be a small GTPase that was associated with plasma adiponectin, insulin, and high-density lipoprotein (HDL) cholesterol levels, obesity, and coronary atherosclerosis [15, 16]. However, its function is still unknown. Our tertiary analysis indicated that ARL15 belongs to the small GTPase superfamily. Subfamilies like Rab and Arf GTPase were reported to be involved in endomembrane trafficking, from the endoplasmic reticulum (ER) to the Golgi in many studies [17-19]. Immunostaining results showed that ARL15 was predominantly localized in the Golgi apparatus [11]. Together with our tertiary analysis, this supports the idea that ARL15 may be involved in endomembrane trafficking. In line with this, Corre *et al.* proposed that ARL15 can influence the channel activity of the Mg^{2+} channel TRPM6, possibly by affecting channel trafficking [9].

Figure 6. Membrane trafficking-related genes expression did not change in *Arl15*^{+/-} mice.

The mRNA expression levels of *Arf1*, *Argef-1*, *Argef-2*, and *Arf6* in the kidney of male (A-D) and female (E-H) *Arl15*^{+/+} (+/+) and *Arl15*^{+/-} (+/-) mice fed with low fat diets (LF) or high fat diets (HF) were measured by RT-qPCR. Results were normalized to *Gapdh* expression (reference gene). *Arf1*, ADP ribosylation factor 1; *Arf6*, ADP ribosylation factor 6; *Argef-1*, ADP ribosylation factor guanine nucleotide exchange factor 1; *Argef-2*, ADP ribosylation factor guanine nucleotide exchange factor 2.

In this study, we demonstrated that *Arl15* mRNA was widely expressed in mice. *Arl15* was highly abundant in white adipose tissue. The white adipose tissue was responsible for adiponectin secretion, which plays an important role in modulating the level of blood glucose and the breakdown of fatty acid [20, 21]. It had been shown that *Arl15* knockdown in differentiated adipocytes resulted in decreased adiponectin secretion and impaired adipogenesis in pre-adipocytes [11]. Together, this suggests that ARL15 was directly or indirectly involved in the regulation of adiponectin function [11]. However, In contrast to the positive correlation of *Arl15* and *Adiponectin* in 3T3-L1 cells [11], our study did not observe changes in mRNA expression level of *Adiponectin* or other metabolism-related genes in *Arl15*^{+/-} mice compare to *Arl15*^{+/+} mice. This may due to the fact that certain signal pathways and/or compensatory mechanisms can be activated to counteract the heterozygous knockout of ARL15.

A recent GWAS analysis demonstrated that ARL15 was associated with urinary Mg²⁺ excretion [9]. Knockdown of *arl15b* expression in zebrafish larvae decreased the Mg²⁺ content compared with controls, which was suggestive of renal Mg²⁺ wasting [9]. Nevertheless, serum and urinary Mg²⁺ levels were normal in *Arl15*^{+/-} mice. A compensatory network may be activated to counteract Mg²⁺ wasting in *Arl15*^{+/-} mice. Although this could not be detected by RT-qPCR, changes in protein expression or function cannot be excluded. For instance, Mg²⁺ reabsorption by TRPM6 in the DCT may be altered by heterozygous knockout of ARL15, given the role of ARL15 in TRPM6 channel function [9]. Therefore, further studies on the protein level and function level should be performed to better understand potential compensatory mechanisms. Alternatively, *Arl15*^{+/-} mice could be faced with low Mg²⁺ diets in order to challenge potential compensation. Corre *et al.* reported that the mRNA expression of *arl15b* increased nearly 70% to deal with Mg²⁺ deficiency in zebrafish [9]. Additionally, ARL15 kidney-specific knockout could be generated to understand more about the function of ARL15 in the kidney.

Taken together, our studies demonstrated that *Arl15*^{+/-} mice possess a normal physiological behavior and no disturbances in Mg²⁺ handling. Thus, to determine whether ARL15 is involved in renal Mg²⁺ handling, additional studies are warranted. Future research should focus on generating ARL15 kidney-specific knockout mice and challenging the mice with low Mg²⁺ diets to further elucidate the physiological and pathological role of ARL15 in Mg²⁺ homeostasis.

Abstract

Cyclin M (CNNM1-4) proteins maintain cellular and body magnesium (Mg^{2+}) homeostasis. Here, we identified using various biochemical approaches that members of the CNNM family are direct interacting partners of ADP-ribosylation factor-like GTPase 15 (ARL15). ARL15 interacts with CNNMs at their carboxyl-terminal conserved cytosolic cystathionine β -synthase (CBS) domains. *In silico* modeling of the interaction using the reported structures of both CNNM2 and ARL15 supports that the small GTPase specifically binds the CBS1 domain. Immunohistochemistry and immunocytochemistry experiments demonstrated that CNNM2 and ARL15 co-localize in the kidney, with both proteins showing subcellular localization in the Golgi-apparatus. Towards understanding the role of this interaction, we found that overexpression of ARL15 in human embryonic kidney 293 (HEK293) cells resulted in complex N-glycosylation of CNNMs. Moreover, Mg^{2+} uptake experiments with stable isotopes demonstrate that there is a significant increase of $^{25}\text{Mg}^{2+}$ uptake upon knockdown of ARL15 in multiple kidney cancer cell lines. Altogether, our results establish ARL15 as a novel negative regulator of Mg^{2+} homeostasis by promoting the N-glycosylation of CNNMs.

Introduction

Mg^{2+} is an essential cation for all living organisms. As co-factor of ATP, Mg^{2+} is involved in over 600 enzymatic reactions and as such it plays important roles in a plethora of biological mechanisms such as DNA transcription, protein synthesis and energy metabolism [1]. Approximately 1% of the body Mg^{2+} content is present in the blood, indicating that the great majority of Mg^{2+} is stored intracellularly in soft tissues and in the hydroxyapatite structure of the bone [2]. Decreased intracellular Mg^{2+} levels suppress cell cycle progression and are consequently associated with cell growth impairment [3]. Recent studies therefore have focused on the regulation of intracellular Mg^{2+} concentration as a central mechanism for cellular metabolism and proliferation [4].

Among the various mechanisms of Mg^{2+} sensing and transport, proteins of the CNNM family were shown to play an important role in the intracellular sensing of the Mg^{2+} availability [5, 6]. The CNNM family has 4 members, which are highly conserved but have different tissue distribution [4-7]. CNNM3 shows a ubiquitous expression pattern, whereas CNNM1, CNNM2, and CNNM4 have the highest expression levels in the brain, kidney, and intestine, respectively [8]. All CNNMs interact with phosphates of the regenerating liver (PRL1-3) via the CBS domain of CNNMs [9, 10]. CNNMs and PRLs have been associated with the progression of breast and colon cancers [10, 11]. Although the exact molecular function of CNNM proteins is under debate [12, 13], it has been shown that engineered and naturally occurring mutations in CNNMs result in decreased Mg^{2+} transport in both cell and animal models [10, 14]. Notably, mutations in *CNNM2* result in renal Mg^{2+} wasting [14].

Recently, a large genome wide association study (GWAS) identified the *ARL15* locus to be associated with urinary Mg^{2+} excretion [15]. *ARL15* is structurally similar to Ras-related GTP-binding proteins, which regulate intracellular vesicle trafficking [16, 17]. Within the kidney, *ARL15* is highly expressed in the thick ascending limb (TAL) and distal convoluted tubule (DCT), like *CNNM2*, where Mg^{2+} reabsorption is tightly regulated [15]. However, the exact function of *ARL15* and the mechanism by which *ARL15* regulates Mg^{2+} homeostasis is still unknown.

In this study, we identified CNNMs as direct interacting partners of *ARL15* by binding to the CBS1 domain of *CNNM2*. We demonstrate that *ARL15* is a negative regulator of cellular Mg^{2+} homeostasis through its modulation of CNNMs glycosylation and the direct correlation of its expression to levels of intracellular Mg^{2+} .

Methods and materials

DNA constructs

Human *CNNM2* cDNA with an in-frame HA tag before *CNNM2* stop codon and an *XhoI* restriction site after *CNNM2* stop codon was amplified using Phusion

polymerase (New England Biolabs, Ipswich, MA, USA) and then the product was cloned into the pCINeo-IRES-GFP vector using *NheI* and *XhoI* (New England Biolabs). To obtain truncated *CNNM2* plasmids, primers (Forward: 5'-CGGCTAGCGCCACCATGATTGGCTGTGGCGCTTG-3' and Reverse 1 (full-length *CNNM2*: 05'-CCCTCGAGCTATGCGTAGTCTGGCAGTCGTATGGGTAACCGGTGATGGCGCCTTCGTTG-3'), Reverse 2 (*CNNM2* transmembrane region: 5'-CCACCGGTCACGTCTCCACCGTC-3'), Reverse 3 (*CNNM2* transmembrane+CBS1 region: 5'-CCACCGGTGTCATCGGGATCCAC-3'), Reverse 4 (*CNNM2* transmembrane+CBS1+link region: 5'-CCACCGGTGTGGTTATAAAATTTGGTGATG-3') or Reverse 5 (*CNNM2* transmembrane+CBS1+link+CBS2 region: 5'-CGGCTAGCGCCACCATGATTGGCTGTGGCGCTTG-3') were synthesized. All primers were purchased from Biolegio BV (Nijmegen, Netherlands). The PCR product was purified using a NucleoSpin® Gel and PCR Clean up kit (Macherey Nagel, Düren, Germany). Subsequently, the truncated *CNNM2* PCR products were cloned into the pCINE-IRES-GFP vector by digestion with restriction enzymes *NheI* (New England Biolabs) and *XhoI* (New England Biolabs).

To obtain C-terminal FLAG-tagged ARL15 and *CNNM* constructs, human coding sequences were amplified with appropriate primers containing attB1 and attB2 recombination site overhangs. Amplification was carried out with KAPA HiFi polymerase using GC buffer (Kapa Biosystems, Wilmington, MA, USA). Amplicons were gel purified and Gateway cloning was used to first recombine the amplicon into pDONR221 vector and then, pDEST26 (Addgene #79275) vector, using Gateway BP or LR Clonase II enzyme mix, respectively (Thermo Fisher Scientific, Waltham, MA, US). Chemically competent DH5α *E. coli* were transformed with pDONR221 and pDEST26 vectors. All constructs were verified by sequence analysis.

Cell culture, transfection and transduction

HEK293 cells were grown in Dulbecco's Modified Eagle Medium (DMEM) (Biowhittaker Europe, Vervier, Belgium) supplemented with 10% (v/v) fetal calf serum (PAA Laboratories, Linz, Austria), non-essential amino acids, and 2 mM L-glutamine at 37 °C in a humidified incubator with 5% (v/v) CO₂ (New Brunswick Galaxy 170s). Cells were seeded 6 hours before transient transfection with Lipofectamine 2,000 (Invitrogen, Breda, The Netherlands), the ratio of DNA: Lipofectamine 2,000 was 1:2.

ACHN, Caki-1, HeLa, RCC4 and SK-RC-39 cells were grown in DMEM, high glucose (Thermo Fisher Scientific) supplemented with 10% fetal bovine serum (FBS) (Thermo Fisher Scientific) and 2 mM GlutaMAX at 37 °C in a humidified incubator with 5% (v/v) CO₂.

For lentivirus production, HEK293T/17 cells were transfected with a 4:2:1 ratio of lentiviral construct of interest: PAX2: VSV-G. 24 hours later, the media was changed. 48 hours later, the media was collected and filtered through a 0.45 µm filter. To infect the cells, media was substituted with HEK293T/17 supernatant containing virus with 8 µg/ml polybrene. 48 hours later, the media was changed to fresh media containing a selection reagent and the selection was carried out for 7 days.

Site-directed mutagenesis

To mutate asparagine 73 (N73) that was predicted to be the site of N-glycosylation of CNNM3 into alanine (A), pDONR221-CNNM3 carrying the wild-type sequence without a stop codon was amplified using a single primer PCR. Amplification was carried out with KAPA HiFi polymerase using GC buffer (Kapa Biosystems, Wilmington, MA, USA). The following primer was used: 5'-GGCCCGGGCTTCGCCgcCAGCTCTTGGTCCTGGGTGG-3', indicating the nucleotides necessary to introduce the mutation in lower-case letters. After amplification, the original plasmid was digested with *DpnI* (New England Biolabs) for 2 hours at 37 °C, which was followed by transformation of chemically competent DH5a E. coli. The construct was verified by sequencing.

Pull down assay

A pull down assay was performed to determine which proteins of mice DCT interact with CNNM2. pGEX-mCNNM2 c-tail-GST was inserted in bacteria to be able to multiply the protein. Afterwards, bacteria were lysed with lysis buffer (150mM NaCl, 5mM EGTA, Triton 1% (v/v), 1mg/ml pepstatin, 1mM PMSF, 5mg/ml leupeptin, 5mg/ml aprotinin, 50mM Tris/HCl, pH 7.5). Glutathione beads (Thermo Fisher, Rockford, IL, USA) were used to purify the samples to obtain only CNNM2 c-tail. The beads were washed with pull down buffer (20mM Tris-HCL pH 7.4, 140mM NaCl, 1 mM $CaCl_2$, 0.2% (v/v) triton-x-100, 0.2% (v/v) NP-40, 1:1000 pepstatin, 1:1000 Aprotinin, 1:400 Leupeptin, 1:100 PMSF) and bacterial lysate was added to the beads followed by an incubation of 3 hours at 4 °C. After incubation, beads were transferred into a new tube and washed with pull down buffer. For kidney tissue, kidneys of 8 PV-GFP mice were dissected and minced in small pieces. The DCT was selected and dissolved in pull down buffer followed by homogenizing of the mixture using ultra turrax. After 30 minutes of incubation on ice, aliquots were taken and centrifuged. Supernatant was added to the beads followed by an incubation overnight rotating at 4 °C. After incubation, beads were washed with pull down buffer, Laemmli and DTT were added, and Western blot was performed. Migration was stopped when the sample was 1 cm in the running gel. Then samples were cut out and measured with mass spectrometry.

Biotin identification (BioID)

BioID was performed as previously described [18]. The graph of ARL15 interacting partners was generated using ProHits-viz [19]. Gene ontology overrepresentation analysis was performed using PANTHER 15.0 [20].

ARL15 model

A model of the structure of ARL15 was generated by simulated annealing as implemented in Modeller [21] using as templates the X-ray diffraction coordinates of the complex between human ARL2 and BART (pdb code 3DOE chain A; 36.3 identity) complex

between murine ARL2 and PDE δ (pdb code 1KSG chain A; 36.3 identity) murine ARF6 (pdb code 6BBQ; 35.67% identity) human ARF6 (pdb code 2A5G; 35.67% identity). Results were monitored in UCSF Chimera [22]. A single structure, displaying the lowest zDOPE [23] score (-0.58) and an RMSD value of 3.54 Å with respect to the closest template, out of 100 results were selected. This structure was subjected to energy minimization using the Amber 14SB force field [24]. A final check was performed with Coot [25] before deposition and the ModelArchive server.

CNNM models

To generate alternative linker conformations, in addition to completing sidechains from a SAXS model, simulated annealing computations were carried out using Modeller 9.3 [21]. 100 conformations were generated, arranged according to their zDOPE scores and tested for collisions with other subunits with UCSF Chimera. At the end, three different conformations were tested. A model of the cytosolic domains of CNNM3 was also generated using the full precursor sequence (NCBI accession code 060093.3) and the XRD coordinates of the CNNM2 cytosolic domains in their flat conformation [26].

Docking models

Docking computations were carried out with benchtop HEX [27] and compared with Brownian dynamics (BD) computations. Hex computations included shape evaluation, in vacuo electrostatics and Decoys As a Reference State (DARS) potentials [28]. In every simulation, 20,000 structures were generated, clustered using a RMSD cut-off value of 3 Å and arranged according to their energies. First 100 were selected for analysis. Post-processing consisted in a short Optimized Potentials for Liquid Simulations (OPLS) energy minimization as implemented in the software.

Brownian dynamics

Docking modeling was complemented with BD computations using the WebSDA server [29] to test if results could be reproduced by other methods. The force-field grids used in BD included all electrostatics and desolvation [30, 31] grids. Charges were added with PDB2PQR tool [32].

200 trajectories of BD computations were run in docking mode. A total of 500 non-redundant complexes were recorded along the computations. Table 1 displays the summary of the clustering analysis of the distinct complexes found. First cluster corresponds to binding to cyclic nucleotide monophosphate-binding homology (CNBH) domains at regions nearby missing structure, so they are considered artefactual. Cluster 2, however, showed the highest population and—on average—displayed lowest energies, and the lowest dispersion of conformations, according to RMSD values with respect to the representative structure.

Glycosidase and tunicamycin treatment

20 µg of protein from SK-RC-39 cells were treated with N-glycosidase F (PNGase F) and Endoglycosidase H (Endo H) (New England Biolabs) according to the manufacturer's instructions. Briefly: protein was denatured at 100 °C for 10 minutes, 1 unit/ul of a glycosidase was added with appropriate buffers and digested at 37 °C for 1 hour. SK-RC-39 cells grown in DMEM were treated with tunicamycin (Sigma-Aldrich, St. Louis, MO, USA) at 1 µg/ml for 8 hours to inhibit N-glycosylation.

Immunohistochemistry

5 µm kidney frozen sections were fixed with formalin and washed with TN buffer (0.1 M Tris/HCl (pH7.6) 0.15 M NaCl). Then, the sections were permeabilized in TN-Triton (TN with 0.1% Triton X-100) for 30 minutes. After incubation, the sections were washed and blocked with TN with 0.5% (w/v) blocking reagent TSA fluorescein system (Perkin Elmer, Waltham, MA, USA) for 30 minutes. The sections were incubated overnight at 4 °C with the following primary antibodies: guinea pig anti-CNNM2 (kindly received from Dr. Muller), rabbit anti-ARL15 (Sigma-Aldrich, St. Louis, MO, USA). For detection, kidney sections were incubated with Alexa Fluor 488 conjugated goat anti-rabbit and Alexa Fluor 596 conjugated goat anti-guinea pig IgG secondary antibodies (Thermo Fisher, Rockford, IL, USA). Images were visualized using AxioCam cameras (Zeiss, Oberkochen, Germany) and AxioVision software (Zeiss).

Immunocytochemistry

HEK293 cells were seeded at a low density on 0.01% (w/v) poly-L-lysine (Sigma, St Louis, MO, USA) coated coverslips and were transfected the subsequent day using Lipofectamine 2000 (Invitrogen, Breda, The Netherlands). Then, the following constructs: pCINEO-CNNM2-HA-IRES-GFP, pLenti6-CNNM3-V5, pDEST26-ARL15-FLAG, and mCherry-Golgi-7 were transfected. 24 hours after transfection, cells were washed with PBS, followed by fixation for 10 minutes using 4% (w/v) methanol-free formaldehyde (ThermoFisher, Waltham, MA, USA) in PBS. Afterwards, cells were permeabilized for 10 minutes in 0.1% (v/v) Triton-X100 and 0.3% (w/v) bovine serum albumin (BSA) (ThermoFisher, Waltham, MA, USA) solution. Subsequently, cells were treated with 50 mM NH_4Cl in PBS in order to reduce the background. Thereafter, cells were washed in PBS followed by blocking in 16% (v/v) normal goat serum (Merck Millipore, Burlington, MA, USA) supplemented with 0.1% (v/v) Triton-X100 for 30 minutes in room temperature. Then, cells were probed with primary antibody diluted in blocking buffer overnight at 4 °C, washed three times and incubated in secondary antibodies for 45 minutes at room temperature in the dark. Cells were washed three times with PBS and subsequently mounted using mounting medium supplemented with 4', 6-diamidino-2-phenylindole (DAPI; Southern Biotech, Birmingham, AL, USA). Images were made using the Zeiss LSM880 (Oberkochen, Germany) and analyzed using the freely available Fiji software [33]. The following antibodies were

used: mouse monoclonal anti-HA (Sigma-Aldrich, St. Louis, MO, USA), mouse monoclonal anti-V5 (Thermo Fisher, Rockford, IL, USA) and rabbit polyclonal anti-FLAG (Sigma-Aldrich, St. Louis, MO, USA), Alexa Fluor 488 conjugated goat anti-rabbit and Alexa Fluor 647 conjugated goat anti-mouse (Thermo Fisher, Rockford, IL, USA).

Western blot

Cells were lysed with lysis buffer containing 1mg/ml pepstatin, 1mM PMSF, 5mg/ml leupeptin, 5mg/ml aprotinin protease inhibitors. The lysis buffer contained 50mM Tris-HCl (pH 7.5), 1mM EDTA, 1mM EGTA, 150mM NaCl, 1mM sodium-orthovanadate, 10mM sodium-glycerophosphate, 50mM sodium fluoride, 0.27M sucrose, 10mM sodium pyrophosphate, 1% (v/v) Triton X-100. Protein concentrations were measured by performing a Bicinchoninic Acid protein assay (BCA) (Fisher Scientific, Hampton, NH, USA) and 20 µg protein were used for Western blot. Blots were then incubated in primary antibody overnight rolling at 4 °C. Primary antibodies were diluted in 1% (w/v) milk diluted in Tris-Buffered Saline and Tween 20 (TBST) as following; anti-HA (Cell Signaling technology, Leiden, The Netherlands), anti-FLAG (Sigma-Aldrich, St. Louis, MO, USA), anti-V5 (Thermo Fisher, Rockford, IL, USA), anti-β-actin (Sigma-Aldrich, St. Louis, MO, USA), all are raised in mice. After washing with TBST, blots were incubated for 1 hour rolling at room temperature (RT) in secondary antibody which was sheep anti-mouse antibody (Sigma-Aldrich, St. Louis, MO, USA). Then, proteins were visualized with Chemidoc (Bio-Rad Laboratories Inc, Hercules, CA, USA). Subsequent analysis was done using Image J [33].

Co-Immunoprecipitation

HEK293 or HeLa cells were seeded and transfected in petri dishes, 24 to 48 hours after transfection, cells were lysed with lysis buffer. BCA assay was performed to determine the protein concentration of the lysates. Input samples were taken to be able to check transfection efficiency by performing Western blot. For co-immunoprecipitation samples, 30 µl/sample protein A/G plus agarose beads (Santa Cruz Biotechnology, CA, USA) were washed with PBS. And 1.5 µl/sample in mouse raised antibody for human HA (Sigma-Aldrich, St. Louis, MO, USA) was added to the beads. For negative control, no antibody was added to the beads. Samples were then incubated for 2 hours rotated at 4 °C. Unbound antibodies were removed by washing with PBS. Then, lysates with the same amount of proteins (as calculated with the BCA test) were added to the beads and incubated overnight rotated at 4 °C. After incubation, lysates and beads were washed with lysis buffer. Then, Laemmli and Dithiothreitol (DTT) were added, and Western blot was performed. For FLAG-tagged protein immunoprecipitation, for each sample, 20 µg of Anti-FLAG M2 affinity agarose gel (Sigma-Aldrich, St. Louis, MO, US) were pre-blocked with 5% (w/v) BSA and 300 µg of total cell lysate (TCL) was pre-cleared with 20 µg of protein A/G agarose mix, for 2 hours at 4°C on a rotator. TCL supernatant was collected and incubated with pre-blocked FLAG beads for 2 hours at 4 °C on a rotator.

ATP production

5,000 kidney cancer cells were plated per well in a 96-well plate and ATP production was measured after growing overnight. CellTiter-Glo 2 kit (Promega) was used in accordance with manufacturer's instructions.

CRISPR-Cas9 experiments

Guide RNA (sgRNAs) targeting ARL15 were cloned into lentiCRISPRv2 plasmid (Addgene #52961) using Golden-Gate Assembly with the Esp3I endonuclease following the standard protocol [34]. For lentivirus production, HEK293T/17 cells were transfected using Lipofectamine 2000 (Invitrogen, Breda, The Netherlands) with 4:2:1 ratio of lentiCRISPRv2:PAX2: VSV-G. 24 hours later, the media was changed. 48 hours later, the media was collected and filtered through a 0.45 μ m filter. To transduce the cells, media was substituted with HEK293T/17 supernatant containing virus with 8 μ g/ml polybrene. 48 hours later, the media was changed to fresh media containing puromycin and the selection was carried out for 7 days.

$^{25}Mg^{2+}$ uptake

ACHN, Caki-1, RCC4 and SK-RC-39 cells were seeded into 12-well plates. Two days after transfection, cells were washed once with basic uptake buffer without Mg^{2+} (125 mM NaCl, 5 mM KCl, 0.5 mM $CaCl_2$, 0.5 mM Na_2HPO_4 , 0.5 mM Na_2SO_4 , 15 mM HEPES/NaOH, pH 7.5), followed by incubation for 0 or 15 minutes at 37°C with basic uptake buffer containing 1 mM $^{25}Mg^{2+}$ (Cortecnet, Voisins Le Bretonneux, France). After incubation, the basic uptake buffer containing $^{25}Mg^{2+}$ was removed and cells were washed with ice cold PBS. Then cells were lysed with 1 ml nitric acid (Sigma Aldrich, St. Louis, MO, USA) which was then diluted in Milli-Q until a nitric acid concentration of 10%. Samples were analyzed with inductively coupled plasma mass spectrometry (ICP-MS).

Cell surface biotinylation

Petri dishes were coated with poly-L-lysine before seeding and transfection. Two days after transfection the cells were washed with PBS-CM (100 ml 10x PBS, 1 mM $MgCl_2$, 0.5 mM $CaCl_2$, pH 8.0 adjusted with NaOH, Milli-Q until total volume of 1,000 ml) followed by adding 0.5 mg/ml Sulfo-NHS-LC-LC-biotin (Thermo fisher scientific, Rockford, USA). After 30 minutes incubation, cells were washed with 0.1% (w/v) PBS-CM BSA and PBS. Cells were then lysed with lysis buffer, and protein concentration was measured with a BCA test. Input samples were taken to be able to check transfection efficiency by performing Western blot. Then, lysates with the same amount of proteins (as calculated with the BCA test) were added with the neutravidin agarose beads (Thermo fisher scientific, Rockford, USA) and incubated overnight rotated at 4°C. After incubation, protein lysates were washed with lysis buffer. Then, Laemmli and DTT buffer were added to samples and incubated at 37°C for 30 minutes before loading the protein samples on SDS-PAGE.

Statistical analysis

Results are expressed as mean \pm standard error of the mean (SEM). Biotinylation, Co-Immunoprecipitation and ATP production results are statistically analyzed by performing one-way ANOVA followed by Tukey as post-test. $^{25}\text{Mg}^{2+}$ uptake results are statistically analyzed by performing a two-way ANOVA followed by Tukey as post-test. Differences with $P < 0.05$ were regarded as statistically significant.

Results

ARL15 is a new binding partner of CNNMs

To identify CNNM2 protein interactions, pull down of mouse CNNM2 carboxyl-terminal region was performed using DCT-enriched kidney lysates, followed by mass spectrometry (Figure 1A). Twenty-four interacting partners of CNNM2 were detected, including ARL15 (Figure 1B). Since ARL15 has been shown to be involved in urinary Mg^{2+} excretion [15], we decided to further explore this particular interacting partner. To confirm the interaction between ARL15 and CNNMs, BiOId of ARL15 was performed and we identified 221 proteins as potential interacting partners of ARL15 and CNNM2, CNNM3 and CNNM4 were among them (Figure 1F). Gene ontology (GO) biological process overrepresentation analysis indicated that Mg^{2+} ion homeostasis was one of the most highly enriched processes (Figure 1C). Immunoprecipitation demonstrated that CNNM3 and ARL15 interact endogenously (Figure 1D). To further confirm this association, co-immunoprecipitation assays were performed with overexpressed ARL15 and the four members of the CNNM family. ARL15 binding was observed to a similar extent for each CNNM protein (Figure 1E). Endogenous PRL-1 and PRL-2, which are well described interacting partners of CNNMs that regulate Mg^{2+} flux [10, 11], also co-precipitated with CNNMs and ARL15 (Figure 1E). The above data indicate that ARL15 is a novel interacting partner of the four members of the CNNM family of Mg^{2+} modulators.

ARL15 interacts with CNNM2 cytoplasmic region

The topology for CNNMs consists of a signal peptide, three transmembrane domains (TM) and an intracellular C-carboxyl containing the CBS and a CNBH domain (Figure 2A) [8]. To determine which domain of CNNM2 is important for the interaction with ARL15, truncated CNNM2 proteins were co-immunoprecipitated with ARL15. The presence of the CBS domains is essential for the binding of ARL15 to CNNM2. The interaction of the proteins decreases by 36% when the CBS2 domain is removed (Figure 2B and 2C). No interaction with the transmembrane domain was observed. These results show that ARL15 interacts with the cytoplasmic portion of CNNM2 and that the interaction is enhanced by the presence of the complete C-terminal region of the protein.

To determine whether the interaction between ARL15 and CNNMs was dependent on Mg^{2+} or not, ARL15 and CNNM were immunoprecipitated in the presence or absence of Mg^{2+} in the lysis buffer. Results showed that adding 1mM Mg^{2+} in the lysis buffer does not affect the association between ARL15 and CNNM2 compared to the condition of the lysis buffer without Mg^{2+} (Figure 2D). In line with this, the binding between ARL15 and CNNM3 was similar in both conditions (Figure 2E).

Docking models of the CNNM-ARL15 interaction

To assess the role of the various cytoplasmic CNNM2 cytosolic domains as targets of ARL15, docking computations were carried out. The coordinates of the flexible linker joining the Bateman and CNBH domains were modelled onto the available X-ray diffraction data of the CNNM2 cytosolic domains. Figure 3 displays the domain arrangement of CNNM2 cytosolic domains (Figure 3A) as well as the electrostatic potential on their surface (Figure 3B). Notably, the linkers joining the Bateman domain to the CNBH display a stretch of basic residues. Best score solutions displayed ARL15 interacting with both CNNM2 monomers. ARL15 was partly inserted into the cleft between the Bateman domains and the CNBH domains (Figure 3C-D). In each of the two symmetric solutions, the total buried solvent accessible surface per partner was 2,175.7 Å², 1,830.8 Å² (932.6 Å² from CBS1, 262.3 Å² from the linker and 344.9 Å² from the CNBH domain) with one of the two CNNM2

monomers and 344.9 \AA^2 (190.6 \AA^2 from CBS1* and 154.3 \AA^2 from CNBH*) for the interaction with the second CNNM2 monomer. Such values are typical of rather stable complexes, and in the upper limit of non-obligate interactions [35]. In addition, the complex displays complementarity of charges at the rim of the interface, as shown in Figure 3D.

As pointed out, the Bateman CBS1 domains contacted with ARL15, in particular that of the first monomer with a surface region defined between α -helix A, the $\beta 1$ - $\beta 2$ hairpin loop and α -helix H1 in one of them, but also contacting the second monomer. Figure 3C shows the lowest energy solution found in different simulations. Other solutions with low energies corresponded to the hydrophobic surface of H0 helix pair, which interacts with the lipid bilayer, and spots of the CNBH domains in which the absence of coordinates from the nearby unstructured regions disclosed an artifactual interaction site, otherwise concealed. Notably, BD computations (Figure 3 E-G, Table 1) yielded results very similar to those displayed herein. Thus, the interaction model herein is compatible with a 1:1 CNNM2:ARL15 stoichiometry. Other sets of solutions targeted the same region, but displayed different orientations of ARL15 towards CNNM2 surface, and were not found in all simulations. The result in Figure 3, however, was hardly dependent on the modelled conformation of the linker—residues 525 to 546 (Figure 3D). Nevertheless, in most simulations several positive residues of the linker mapped near the interface. As CNNM3 has been reported to bind ARL15 with an affinity higher than that for CNNM2, HEX docking simulations were also performed using a CNNM3 model (Figure 3 E-G). Notably, ARL15 targeted the same site in CNNM3 as does in CNNM2, though the orientation differs by a slight rotation of ARL15.

ARL15 and CNNM co-localize in the perinuclear region and in kidney DCTs

The subcellular localization for the ARL15-CNNM complex was determined by immunocytochemistry in HEK293 cells. Overexpression of the mCherry-tagged Golgi-marker Beta-1,4-Galactosyltransferase 1 (B4GALT1) showed co-localization with ARL15 and CNNM2 in HEK293 cells, suggesting that the function of ARL15 is exerted within the perinuclear region containing the endoplasmic reticulum (ER) and the Golgi-apparatus (Figure 4A). Similar results were obtained with ARL15 and CNNM3, confirming that the proteins predominantly co-localize in Golgi (Figure 4B).

Since CNNM2 has been implicated in Mg^{2+} transport in the DCT segment of the kidney [8], we investigated whether ARL15 co-localizes with CNNM2 in this segment of the nephron (Figure 4C). Immunostaining results showed that CNNM2 staining was concomitant with ARL15 staining in mouse kidney sections. One of the ARL15 interacting partners identified using BioID was RPN1 (ribophorin I) (Figure 1F). RPN1 is part of the oligosaccharyltransferase complex that is involved in N-glycosylation and is found in the ER [37]. To confirm the interaction, co-immunoprecipitation assays with overexpressed CNNM3, ARL15, and RPN1 were performed (Figure 4D). CNNM3 interacted with RPN1 and ARL15, corroborating the localization of the three proteins to the ER as well (Figure 4D).

CNNM3 N-glycosylation is modulated by ARL15 and Mg^{2+}

CNNM2 has been previously shown to have an N-glycosylation site close to its amino (N)-terminus [8]. Using NetNGlyc [38], N-glycosylation sites were predicted in CNNM1, CNNM2, CNNM3, and CNNM4. The N-glycosylation site is conserved on their extracellular domain (CNNM1 N97, CNNM2 N112, CNNM3 N73, and CNNM4 N85). To confirm that CNNM3 does indeed have an N-glycosylation site similar to CNNM2, the predicted N73 was mutated to A (N73A mutant). Compared to wild-type CNNM3, the N73A mutant migrated further down the gel, which is indicative for the loss of N-glycosylation (Figure 5A). Endo H and

PNGase F were used to characterize the type of glycans attached to CNNM3 (Figure 5B). When wild-type CNNM3 was treated with Endo H, which cleaves oligomannose glycans, the bottom band of the doublet shifted further. Cleavage with PNGase F shifted all bands of CNNM3 to a lower molecular mass, indicating that the top band represents the hybrid/complex glycoform (Figure 5A).

Since one of the enriched GO biological processes identified in ARL15 BioID was “Protein N-linked glycosylation via asparagine” (Figure 1C), we aimed to assess the effect of ARL15 on CNNM3 N-glycosylation. To this end, four different kidney cancer cell lines were used: Caki-1 and RCC4 as well as ACHN and SK-RC-39, belonging to renal clear cell carcinoma and papillary renal cell carcinoma, respectively. ARL15 was stably overexpressed in these four cell lines and the pattern of endogenous CNNM3 bands was evaluated.

In all four cell lines, overexpression of ARL15 resulted in the increase of hybrid/complex glycoform and a decrease in oligomannose glycoform of CNM3 (Figure 5C). Using SK-RC-39 cells, an interplay between ARL15 expression and Mg^{2+} concentration in the growth media was observed (Figure 5D). Lack of Mg^{2+} resulted in an increase of oligomannose CNM3 glycoform. Additionally, CRISPR knockout of ARL15 led to a decrease of complex glycoform of CNM3 as can be seen in the last two lanes (Figure 5D).

ARL15 affect Mg^{2+} flux and ATP production

To study whether ARL15 regulates CNM-dependent Mg^{2+} transport, its effect on Mg^{2+} transport capacity was determined using the stable $^{25}Mg^{2+}$ isotope. Stably transduced kidney cancer cells with overexpression or CRISPR-mediated knockout of ARL15 were used. Overexpression of ARL15 decreased $^{25}Mg^{2+}$ uptake, while ARL15 knockout increased $^{25}Mg^{2+}$ significantly, more than 3-fold in RCC4 and SKRC39 cells (Figure 6A).

Figure 6. ARL15 affects Mg^{2+} flux and ATP production.

Results are the mean \pm SEM of 3 independent experiments. sg, Single guide; Scr, Scramble; OE, Overexpression; ARL15, ADP ribosylation factor like GTPase 15; CNNM, Cyclin M.

Since multiple enzymes involved in ATP production by using Mg^{2+} as a cofactor and ATP is bound to intracellular Mg^{2+} to form Mg-ATP [1], we decided to assess the impact of Mg^{2+} influx on ATP production. In RCC4 and SK-RC-39 cells, overexpressing ARL15 resulted in a significant decrease in ATP production (Figure 6B).

Endogenous cell surface expression of CNNM3 was detected in SK-RC-39 cells with overexpression or CRISPR-mediated knockout of ARL15. The complex N-glycosylated CNNM3 glycoform runs at approximately 95kDa, oligomannose glycoform of CNNM3 runs at around 90kDa. Results demonstrated that plasma membrane expression of CNNM3 was not altered in the presence or absence of ARL15 (Figure 6C and 6D). However, the oligomannose CNNM3 glycoform was observed at the plasma membrane in the ARL15 knockout, compared to the ARL15 scramble group.

Discussion

In this study, we identified ARL15 as a novel interacting partner of CNNMs. ARL15 binds to CNNMs in the ER and regulates their complex N-glycosylation in the Golgi system (Figure 7). Our data suggest that the complex N-glycosylation of CNNMs reduces their activity at the plasma membrane, as reflected in a reduced $^{25}Mg^{2+}$ uptake in renal carcinoma cells. As such, ARL15 may affect cellular Mg^{2+} homeostasis and energy metabolism.

ARL15 is a member of the superfamily of ARF-like (ARL) proteins, which have been functionally characterized as small GTPases. Although ARL15 has been relatively scarcely studied to date, many studies have demonstrated that other ARL and ARF proteins are involved in vesicle trafficking [39]. Our immunocytochemistry results in HEK293 cells demonstrated that ARL15 is predominantly localized in the Golgi system (Figure 4), which is in line with previous reports of ARL15 in 3T3-L1 pre-adipocytes [40]. Moreover, proximity labeling of ARL15 identified many Golgi-specific proteins (Figure 1F).

However, the localization with RPN1, a protein of the oligosaccharyltransferase complex, suggests that the interaction between ARL15 and CNNMs is already formed in the ER. Indeed, several ARF (-like) proteins, e.g. ARF1 and ARF3, have been shown to regulate ER-to-Golgi trafficking [41].

The main finding of our study is that ARL15 binds CNNMs and modulates their activity via N-glycosylation. Biosynthesis of glycoproteins commences in the ER, where a pre-assembled oligosaccharide is bound onto the nascent protein by oligosaccharyltransferases. After passing the ER, a series of reactions further assemble the glycan in the medial-Golgi and maturation takes place in the trans-Golgi. Three different types of N-glycans are commonly present on proteins; oligomannose, hybrid and complex N-glycans. Our results demonstrate that ARL15 stimulates the formation of complex N-glycans on CNNMs. Although ARL15 does not possess the enzymatic capacity to change the glycosylation *per se*, we have identified several proteins of the oligosaccharyltransferase

complex in our BioID experiments (e.g. DPM1, RPN1, LMAN1, STT3A and STT3B) (Figure 1F). Moreover, protein N-glycosylation was among the enriched GO-terms in our analysis. We hypothesize that trans-Golgi trafficking via ARL15 is an essential step in the complex glycosylation of CNNMs. A similar mechanism has been postulated for ADP-ribosylation factor guanine nucleotide-exchange factor 1 (ARFGEF1), which regulates the N-glycosylation and trafficking of integrins [42].

Figure 7. Summary of the effect of ARL15•CNNM complex on Mg^{2+} flux.

In the presence of ARL15, it interacts with CNNMs in the ER and Golgi, resulting in the complex N-glycosylation of CNNMs, which in turn decreases Mg^{2+} uptake. In the absence of ARL15, CNNMs are found in less complex glycoforms, which result in increased Mg^{2+} uptake. ER, Endoplasmic reticulum; ARL5, ADP ribosylation factor like GTPase 15; CNNM, Cyclin M.

The N-glycosylation of CNNMs is essential for their plasma membrane expression. CNNMs contain a single N-glycosylation site in the extracellular N-terminal region [8]. Mutation of the N73 residue to A in CNNM3 completely abrogated its membrane expression (Figure 5A). Similar results were previously obtained for N112 residue in CNNM2 [8]. In this study, we demonstrated that not only the presence of, but also the composition of the glycan is essential for the protein function. ARL15 overexpression resulted in a complex-glycosylation of CNNM3, which was accompanied by a significant reduction of $^{25}Mg^{2+}$ uptake. *Vice versa*, ARL15 downregulation resulted in a high-mannose glycan and increased $^{25}Mg^{2+}$ uptake. Altogether, we propose a model in which the composition of the N-glycan affects CNNM activity.

Multiple roles for N-glycosylation of plasma membrane proteins have been described, ranging from effects on membrane trafficking, membrane stability and protein degradation [43, 44]. In our experiments, neither ARL15 overexpression nor ARL15 downregulation affected the plasma membrane expression of CNNM3 (Figure 6C), suggesting that membrane trafficking of CNNM3 is not affected by ARL15. Consequently, changes in N-glycosylation may directly affect the activity of CNNM3 at the plasma membrane. It has been extensively described that N-glycans interact with glycan-binding proteins in the extracellular spaces, such as lectins. Lectin-glycan interactions are involved in many biological cellular processes such as apoptosis, differentiation as well as regulation of membrane transport [45]. Indeed, binding of lectins and other glycan-binding proteins has been shown to regulate TRPV5-mediated Ca^{2+} transport [46, 47]. Whether the binding of lectins explains the changes in CNNM3 activity remains to be defined.

The interaction model that we developed is compatible with a 1:1 CNNM2:ARL15 stoichiometry. ARL15 interacts with the Bateman CBS1 domains, in particular with a surface region defined between α -helix A, the β 1- β 2 hairpin loop and α -helix H1. Indeed, co-immunoprecipitation experiments confirmed that the CBS domains are essential for ARL15 binding (Figure 2B). Overall, the interaction surface is small (355 Å, *ca* 700 Å of surface burial) and presents a core of hydrophobic and polar residues surrounded by charged ones. Interestingly, the positive-charged residues present in the CNNM2 docking site is complementarity to the negative-charged surface of ARL15 (Figure 3). Notably, no overlap is observed between the binding site of ARL15 and PRL, which mostly binds CBS2 by its long loop region comprising β 5 and β 6 [26].

The identification of ARL15 as a novel regulator of CNNM activity is of particular interest in the DCT segment of the kidney. In the DCT, transient receptor potential cation channel subfamily M member 6 (TRPM6) facilitates apical Mg^{2+} transport [48]. Basolateral Mg^{2+} extrusion in the DCT is regulated by CNNM2. Consequently, mutations in *CNNM2* and *TRPM6* have been shown to cause renal Mg^{2+} wasting in patients [14, 49, 50]. Interestingly, the ARL15 locus was recently associated with urinary Mg^{2+} wasting in a GWAS [15]. In the same study, TRPM6 channel activity was shown to be significantly increased in the presence of ARL15 [15]. Our results demonstrate that ARL15 also binds CNNM2, suggesting that both the apical and basolateral Mg^{2+} transport mechanisms are simultaneously regulated. These findings explain how ARL15 determined urinary Mg^{2+} excretion.

Interestingly, overexpression of ARL15 resulted in decreased ATP levels (Figure 6B). Intracellular Mg^{2+} and ATP are closely associated, as ATP must be bound to this cation to be biologically active [1]. Indeed, previous experiments have shown that PRL2 knock-down decreased intracellular Mg^{2+} levels, reduced intracellular ATP levels and regulated cellular metabolism [4]. Given that ARL15 overexpression reduced CNNM-mediated Mg^{2+} uptake, the expression of ARL15 may indirectly regulate cellular metabolism. Indeed, ARL15 has been associated with a wide range of metabolic parameters and diseases

in GWAS, including adiponectin, high-density lipoprotein, diabetes mellitus and body shape [51-56]. As these studies did not analyze Mg^{2+} status as a modifying factor, it cannot be excluded that ARL15 has additional functions that explain these associations. Indeed, ARL15 has been demonstrated to modify the insulin-signaling pathway in myotubes [57].

Overall, our work establishes complex N-glycosylation of CNNMs as an essential process to regulate their activity. This crucial post-translational modification promoted by ARL15 on CNNMs adds to recent mechanisms of CNNMs modulation such as their circadian rhythm expression and their regulation by Mg^{2+} -sensitive translation [4, 58]. The increasing complexity of CNNMs regulation provides a dynamic system to ensure the correct levels of intracellular Mg^{2+} during metabolic changes and cell requirements.

General discussion

Introduction

Sodium (Na^+), calcium (Ca^{2+}) and magnesium (Mg^{2+}) homeostasis plays a key role in a variety of physiological processes in the human body, such as cellular signal transduction, cell metabolism, bone development, enzymatic activity, neuronal conduction and excitability [1-3]. The final concentration and excretion of these electrolytes in the urine is determined by the kidneys through the reabsorption from the pro-urine into the bloodstream [2]. Paracellular and transcellular transport of electrolytes in the proximal tubule (PT), thick ascending limb of loop of Henle (TAL), distal convoluted tubule (DCT), connecting tubule (CNT), and collecting duct (CD) account for the reabsorption processes [4-6]. In particular, this is facilitated by *i)* cation-selective ion transporters, *ii)* endocrine and paracrine hormones, and *iii)* sensors that are sensitive to intra- or extracellular Na^+ , Ca^{2+} , and Mg^{2+} fluctuations [7, 8]. Abnormal regulation of these processes is linked to a variety of diseases such as hypertension, diabetes, kidney stone formation and hypomagnesemia. The purpose of this thesis was to investigate the regulation of Na^+ transporters in the kidney during treatment with sodium-glucose transport protein 2 (SGLT2) inhibitors, to develop Ca^{2+} -binding peptides that may control the urinary Ca^{2+} concentration in hypercalciuria and kidney stone formation, and to study new players involved in renal Mg^{2+} handling.

6

Na^+ handling in the proximal tubule in diabetes and hypertension

The role of potential Na^+ compensatory mechanisms for SGLT2 inhibitors as cardiovascular protective therapies.

In the last decades, SGLT2 inhibitors have become novel and effective type of anti-hyperglycemic drugs that increase glucosuria and ameliorate glycemic control. In addition to their glucose lowering effect, SGLT2 inhibitors can alleviate blood pressure (BP) by reducing systolic blood pressure (SBP) by 3-5 mmHg [9-11]. While it is likely in part due to associated natriuresis and polyuria, the molecular mechanism behind it is still not well documented. In **Chapter 2**, mice with high fat feeding were administrated the SGLT2 inhibitor dapagliflozin (DAPA) to investigate its effect on renal Na^+ handling. These mice exhibited increased blood glucose levels that were alleviated upon 18-day DAPA treatment. Our results showed that the expression of the sodium-phosphate cotransporter (NaPi-2a) and sodium-hydrogen antiporter 3 (NHE3) is upregulated in the kidneys of DAPA-treated mice.

The influence of SGLT2 inhibitors on the function and expression of NaPi-2a and NHE3 is controversial. In 2018, Blau *et al.* found that the serum phosphorus level is increased in volunteers treated with the SGLT2 inhibitor canagliflozin [12]. This increased level of serum phosphorus was associated with an increased reabsorption of phosphate in the PT [13], which would be in line with the increased expression of NaPi-2a in our study. In contrast to

these findings, Thrailkill *et al.* demonstrated that canagliflozin treated diabetic mice exhibit no altered expression levels of NaPi-2a compared with vehicle treated diabetic mice [14]. The following reasons may explain the difference. First, Thrailkill *et al.* only used streptozotocin (STZ) to induce hyperglycemia [14], while we exposed the mice to a high fat diet prior to STZ administration to induce hyperglycemia. Second, canagliflozin was administered for 10 weeks to diabetic mice in their study [14], whereas we treated the mice with DAPA for 18 days.

Interestingly, Pessoa *et al.* previously showed that SGLT2 and NHE3 are functionally interdependent [15]. Glucose promotes NHE3-regulated bicarbonate transport in the PT of Wistar rats, which could be inhibited by perfusion with the SGLT inhibitor phlorizin [15]. Immunostaining results showed that NHE3 was co-localized with SGLT2 instead of SGLT1 in the PT [15]. While they performed stationary *in vivo* microperfusion to rat proximal tubules with phlorizin and sugars, and found that phlorizin inhibited NHE3 activity, gene or protein expression levels were not examined [15]. Nevertheless, NHE3 and SGLT2 seem to be directly or indirectly coupled in the PT [15]. In addition, several studies have reported that alterations of renal NHE3 activity and expression are related to BP changes [16-18]. The BP is decreased in *Nhe3* knockout mice compared to their wildtype littermates [16]. Transgenic mice with NHE3 overexpression exhibited elevated BP, together with decreased urinary water and Na⁺ excretion [17]. Moreover, the activity and protein levels of NHE3 were found to be significantly increased in spontaneously hypertensive rats compared to Wistar-Kyoto (WKY) rats, which will probably lead to renal Na⁺ retention [18]. In line with our results, another study also demonstrated that luseogliflozin treatment increases the protein expression levels of NHE3 in spontaneously hypertensive rats [19]. While there were no plasma or urine Na⁺ measurements in our study, it is most likely that increased expression of NHE3 and NaPi-2a functions as compensation for the decreased Na⁺ reabsorption by SGLT2, which may lead to Na⁺ retention. However, it is still uncertain to which magnitudes the NHE3 and NaPi-2a upregulation influences the urinary Na⁺ excretion and urine volume.

Notably, several studies reported that the BP reduction effect of SGLT2 inhibitors always occur in the early phase of the treatment [20, 21]. Indeed, SGLT2 inhibitor-induced natriuresis was observed shortly after the start of the SGLT2 inhibitor treatment in several clinical studies [22-25]. Similarly, canagliflozin has been shown to increase urine volume in type 2 diabetic patients in the beginning of the treatment [24, 26-29]. Though, the diuretic and natriuretic effects of SGLT2 inhibitors seem to be transient [19, 30]. In the beginning of treatment, SGLT2 inhibitors result in natriuresis [31], which will lead to increased distal Na⁺ delivery to the macula densa [32, 33]. Then, the decreased hyperfiltration, afferent vasoconstriction, and tubuloglomerular feedback will be triggered, through which the BP is decreased [34-36]. In our study, we found that NHE3 and NaPi-2a expression were upregulated. This will result in the decreased Na⁺ delivery to the macula densa, which may inhibit the BP reduction effect of DAPA. In addition, the loss of Na⁺ and water will activate the renin-angiotensin-aldosterone system (RAAS) in long term treatment

(Figure 1) [31]. This could explain why SGLT2 inhibitors reduced BP in the early phase of treatment. Therefore, clinical studies can combine SGLT2 inhibitors with RAAS blockade to better decrease BP in type 2 diabetes patients who suffer from hypertension [37, 38]. Weber *et al.* demonstrated that BP was significantly decreased in a combined DAPA and angiotensin-converting enzyme (ACE) inhibitor treated group compared to the placebo and ACE inhibitor treated group [37]. In another study, Kojima and colleagues addressed that combination treatment of luseogliflozin with lisinopril, which is an angiotensin-converting enzyme inhibitor, significantly reduced BP compared to lisinopril alone [38]. The current thought of SGLT2 inhibition on renal Na^+ handling is summarized in Table 1 and 2.

Figure 1. Mechanism of the potential Na^+ compensatory effect in the proximal tubule upon SGLT2 inhibition on the feedback of macula densa.

SGLT2 inhibitor (Dapagliflozin) treatment may lead to reduced Na^+ and glucose reabsorption in the PT (1), which activates the compensatory expression of NHE3 and NaPi-2a in the PT (2). Increased NHE3 and NaPi-2a may partially prevent the Na^+ loss due to SGLT2 inhibition, which results in decreased distal Na^+ delivery to the macula densa and inhibited tubuloglomerular feedback activity (3). Ultimately, this might lead to Na^+ retention, activation of the renin-angiotensin-aldosterone system, and inhibition of the blood pressure reduction effect of dapagliflozin (4). SGLT2, sodium-glucose cotransporter protein 2; G, glucose; NHE3, sodium-hydrogen antiporter 3; NaPi-2a, sodium-coupled phosphate transporter type 2a; GLUT2, glucose transporter 2; NBC, sodium-bicarbonate cotransporter; CA, carbonic anhydrase; RAAS, renin-angiotensin-aldosterone system.

Interestingly, we did not observe changes in the expression of the sodium-potassium-chloride cotransporter (NKCC2), sodium-chloride cotransporter (NCC) and epithelial sodium channel (ENaC) in the TAL, DCT, and CD, respectively. This seems surprising since inhibition of Na^+ reabsorption in the PT is expected to turn on compensatory mechanisms and to activate Na^+ transporters in the more distal parts of the nephron. For example, the expression of NCC is significantly increased in spontaneously hypertensive rats upon 13 weeks of treatment with luseogliflozin [19]. The discrepancy between our studies may be due to the fact that DAPA treatment was only 18 days. In response to water loss and reduced Na^+ delivery at the distal tubule in the long term treatment, the expression of Na^+ transporters may increase to compensate for Na^+ loss, and renin release will be increased from the juxtaglomerular cells which can result in the activation of RAAS [39].

Taken together, **Chapter 2** focused on the compensatory expression of Na^+ transporters in the local and downstream segments of the nephron in response to DAPA treatment. In order to better alleviate high BP in type 2 diabetic patients with long-term SGLT2 inhibitor treatment, it is interesting to isolate and analyze exosomes in urine samples to investigate the effect of the treatment with SGLT2 inhibitors on the expression of Na^+ transporters (NKCC2, NCC, and ENaC (α , β , γ)) in the distal part of the nephron. Next, certain inhibitors can be used to block the individual Na^+ transporters that are predominantly (up) regulated in type 2 diabetes patients.

Hypercalciuria in kidney stone disease in Henle's loop

Kidney stone prevention through a novel Ca^{2+} -binding peptide

Kidney stones are mineral and acid salts that are formed in the urinary tract in the kidney [40]. The majority of stones consist of Ca^{2+} oxalate and Ca^{2+} phosphate [41]. Although medical therapy has largely improved kidney stone treatment, the recurrence rate after the first stone formation is still very high [42]. Therefore, we investigated our out-of-the-box idea to develop a potentially better remedy for treatment of kidney stones in **Chapter 3**.

This idea is based on nature's EF-hand motif, which is present in a large number of Ca^{2+} -binding proteins and is involved in intracellular Ca^{2+} -binding [43]. The structure of an EF-hand contains two alpha helices connected by a Ca^{2+} -binding loop of 12 residues (Figure 2B). The Ca^{2+} -binding affinities of various EF hands have been studied in detail, and several variations were made to residues of the Ca^{2+} -binding loop that result in changes in Ca^{2+} -binding affinities [44]. With further optimization, we aimed to generate an EF-hand containing peptide that *i*) exhibits Ca^{2+} binding capacity in the renal supersaturation region ($\sim 5\text{-}10$ mmol/L free Ca^{2+}), namely the limb of Henle's loop, but remains inert in the bloodstream (~ 1.2 mmol/L free Ca^{2+}); *ii*) is not toxic to cells and has a good biosafety profile for ultimate *in vivo* treatment; and *iii*) exhibits minimal uptake/reabsorption by proximal tubule cells.

As such, several small Ca²⁺-binding peptides (around 20-30 residues) were developed in our study. One peptide, Ac-DKNGDGYIDAAE-NH₂, demonstrated a dose-dependent binding affinity to Ca²⁺ in the millimolar range. This peptide was developed based on the study of Reid *et al.* [74]. These authors developed an amino acid sequence (α-helix-DKNGDGYISAAE-α-helix) which has a micromolar range Ca²⁺-binding affinity (K_d=58.8 μmol/L) [74]. By using the Ca²⁺- binding loop (DKNGDGYISAAE) of their amino acid sequence as a template, we changed the amino acid at position 9 from S to D. Hereby, our data is in line with earlier studies showing that acidic residues paired on the x axes in the chelating positions of the loop (in bold in our peptide sequence: **DKNGDGYIDAAE**, Figure 2B), together with charged D on the z position are important for determining Ca²⁺-binding affinity [74, 75]. In comparison with the study of Reid *et al.* [74], the Ca²⁺-binding affinity of our peptide is decreased. This could be explained by the fact that the peptide in our study is shorter than the Ca²⁺-binding peptide developed by Reid *et al* [74]. A similar observation has been documented on peptides from EF-hand proteins, showing that absence of the flanking helices reduced Ca²⁺-binding affinity [76].

Although, the peptide-based treatment has become a promising therapeutic method [77], the potential peptide toxicity remains a bottleneck in the development of peptide-based remedies [78]. Therefore, we tested the toxicity of the designed peptide and demonstrated that cell viability was not affected by this peptide (Ac-DKNGDGYIDAAE-NH₂) in human kidney-2 (HK-2) proximal tubular cells. By calculating and comparing the composition of the amino acid sequence in toxic and non-toxic peptides, Gupta *et al.* demonstrated that the average amino acid composition in toxic peptides contains C in the highest amount, followed by N and P [79]. The average amino acid composition of I, K, L, and R in the toxic peptides are very low [79]. The residues C and P are not present in the peptide we selected. Although residue N is present, it is close to the amino-terminus of the peptide. Gupta *et al.* found that N is frequently present in the carboxyl-terminus of toxic peptides [79]. Interestingly, by counting the cumulative difference between the average amino acid composition of preferred residues in the toxic and non-toxic peptides, A, I, V, and F were shown to be ample in non-toxic peptides [79]. Likewise, A and I are present in the peptide we selected. Together, these suggest that the peptide likely has a good safety profile in terms of toxicity. But success of a peptide in a therapeutic setting depends on many other factors including stabilization, aggregation behavior, circulation time, renal clearance, immunogenicity, which need to be experimentally determined.

Due to the small size, the peptide is expected to be freely filtered. However, it should overcome uptake by proximal tubular cells in order to reach the site of action, the limb of Henle's loop. In our study, we found that the selected peptide exhibited mild cellular uptake in HK-2 cells. In the PT, low molecular weight proteins or peptides can be taken up through multiligand receptors [80-82] or apical endocytic pathway [83]. Vegt and colleagues injected radiolabelled peptides in megalin-deficient mice and addressed that a significantly lower amount of peptide was taken up in the kidneys of megalin-deficient mice compared to wildtype mice [84]. This suggests that megalin plays an important role in the renal peptide reabsorption [84]. HK-2 cells are commonly used since the cellular parameters are rather similar to the physiology of renal proximal tubular cells [85]. Therefore, the peptide uptake in the HK-2 cells provides insight that the peptide we designed may also be taken up by the PT in mice or humans. Though, it has to be considered that the observed dose-dependent uptake of the Ca²⁺-binding peptide might also be caused by force-feeding cells with high amounts of the peptide. It was significantly less in comparison to a control cell-penetrating peptide that has been reported be taken up through endocytosis [86] or direct translocation [87, 88]. Importantly, Vegt *et al.* demonstrated presence of radiolabelled peptides in the urine of wildtype mice, yet at lower amounts than the megalin-deficient mice. And radioactivity did not differ significantly in the bloodstream and most other organs, except for the kidney between these mice [84]. This study provides evidence that peptides can reach the limb of Henle's loop. Hence, future *in vivo* studies should assess renal clearance in addition to the tissue distribution, immunogenicity, and efficacy of this peptide in animals.

For such future studies, it is crucial to establish a mouse model with kidney stone disease. **Chapter 3** described a first approach by treating healthy male C57BL/6J mice with 1% (v/v) ethylene glycol (EG) via drinking water for 28 days. While EG is known to induce Ca^{2+} deposits in animals [89], these were not present in the mice from our study. This could be due to the fact that hypercalciuria was not induced in high Ca^{2+} diet treated mice, the urinary pH was similar between the normal Ca^{2+} and high Ca^{2+} diet treated groups, or that C57BL/6J mice had the capacity to prevent stone formation in the kidney [90]. Notably, Ca^{2+} deposits were present in Swiss albino mice administrated with 0.75% (v/v) EG in the drinking water for 28 days [91]. A difference in genetic background may explain the discrepancy. Additionally, Okada and co-workers successfully induced Ca^{2+} oxalate crystal deposits in C57BL/6J mice by injecting glyoxylate intra-abdominally [90]. Generating transgenic mouse is another tool to induce kidney stones *in vivo*. In 2004, Wesson and colleagues showed that EG in the drinking water of Tamm-Horsfall protein (THP) knockout mice results in Ca^{2+} deposits in the kidneys, and not in the kidneys of wildtype mice [92]. Finally, rats could also be considered for our future study as kidney stone formation in rats was shown to share similarities with kidney stone formation seen in humans, such as the oxalate metabolism process [93]. Moreover, EG was also widely and successfully used in several rat studies [89, 93, 94]. Upon identifying the optimal kidney stone animal model, injection of the peptide will be performed to investigate its biodistribution, safety, and efficacy by repeated administration in a kidney stone animal model (Figure 2A and C).

Together, our study provided a first step towards developing a Ca^{2+} -binding peptide with supersaturation-specific Ca^{2+} buffering ability and set up a systematic methodology for generating a kidney stone animal model for future testing.

Figure 2. Kidney stone prevention through a novel Ca^{2+} -binding peptide.

A, the kidney consists of ~1 million nephrons as schematically depicted below, with the different segments color-coded. B, schematic representation of the Ca^{2+} -binding EF-hand structure, with the tested peptide sequence underneath. C, proposed assessment for functional consequences of the Ca^{2+} -binding peptide (orange) in the loop of Henle of an animal model that is prone to stone formation. PT, proximal tubule; TAL, thick ascending limb of loop of Henle; DCT, distal convoluted tubule; CNT, connecting tubule; CD, collecting duct.

Fine tuning of Mg^{2+} reabsorption in the distal convoluted tubule

Identification of a novel gene, *ARL15*

Mg^{2+} is one of the most important cations for energy metabolism and multiple enzymatic reactions involved in DNA and protein synthesis [95]. It is filtered by the glomerulus and is mainly reabsorbed in the TAL and DCT of the kidney [96]. A genome-wide association study (GWAS) identified a novel gene, ADP ribosylation factor like GTPase 15 (*ARL15*), to be associated with urinary Mg^{2+} excretion in seven European cohorts [97]. Other GWAS

demonstrated that variation at the *ARL15* locus is also associated with fasting insulin levels, plasma adiponectin levels, and triglyceride concentrations [98-101]. The role of *ARL15* in the regulation of adiponectin and adiponectin receptor I and insulin signaling was confirmed by *in vitro* studies [102, 103]. Interestingly, we found that *Arl15* mRNA and protein levels are most abundant in mouse white adipose tissue, which is the main site of adiponectin secretion [104, 105]. Furthermore, Rocha *et al.* demonstrated that *Arl15* knockdown in differentiated adipocytes results in decreased mRNA levels of *Adiponectin*, and impaired adipogenesis in pre-adipocytes [106]. In contrast, our study in **Chapter 4** did not show changes in mRNA expression of *Adiponectin* or other metabolism- or Mg^{2+} -related genes in *Arl15* heterozygous (*Arl15^{+/-}*) mice. Alterations in serum electrolytes levels and 24 hours urinary electrolytes excretion were not found in *Arl15^{+/-}* mice compared to *Arl15* wildtype (*Arl15^{+/+}*) mice. Certain compensatory mechanisms may be activated to counteract for the heterozygous knockout of *ARL15*, since *Arl15* knockout mice are lethal after birth. Although compensatory mechanisms could not be detected by RT-qPCR in our study, we cannot exclude changes in protein expression or activity. A similar study on the ADP-ribosylation factor (ARF)-related protein 1 (ARFRP1), which shares 30.8% similarity to *ARL15*, showed that heterozygous *Arfrp1* (*Arfrp^{+/-}*) mice developed normally whereas homozygous *Arfrp1* knockout (*Arfrp1^{-/-}*) mice exhibited embryonic lethality [107]. Interestingly, mice with specific deletion of *Arfrp1* in adipocytes showed a lipodystrophic phenotype and enhanced lipolysis in adipocytes [108]. In light of these studies, additional experiments should focus on investigating protein levels of *ARL15*-related proteins to better understand the potential compensatory mechanisms. Moreover, adipocyte-specific and kidney-specific *Arl15* knockout mice can be generated and challenged with various diets to explore the role of *ARL15* in metabolism and renal electrolyte handling.

Exploring the novel function of *ARL15* by BioID

In **Chapter 4**, we studied this novel gene and investigated its potential role in the kidney. I-TASSER tertiary structure prediction confirmed that *ARL15* belongs to the small GTPase superfamily. Other members of this superfamily, like Rab and Arf, are known to be involved in vesicle trafficking from the endoplasmic reticulum (ER) to the Golgi [109].

ARL15 shares 33.5% similarity with ARF6, which is localized in the plasma membrane [110] and intracellular compartment [111]. Immunostaining results from our study and Rocha *et al.* proved that *ARL15* is localized in the Golgi complex, the plasma membrane and intracellular compartment of 3T3-L1 cells [106]. Other studies demonstrated that ARF6 is involved in endocytic vesicular transport [112] and increased the cell surface expression of transferrin [113]. In accordance with this, Corre *et al.* showed that *ARL15* increases the activity of the Mg^{2+} channel transient receptor potential melastatin 6 (TRPM6), probably by influencing its trafficking [97]. In **Chapter 5**, Biotin identification (BioID) results revealed that *ARL15* interacts with TRPM7, a close homologue of TRPM6. In agreement with this, Donate-Macián *et al.* discovered that *ARL15* interacts with another

TRP family member, TRPV2, by protein-protein interaction prediction [114]. Additionally, ARL15 interacts with amino acid transporters, Ca^{2+} transporters, potassium (K^+) transporters, and other metal ion transporters including zinc (Zn^{2+}) transporters (**Chapter 5**). Together, these findings broadened the basic knowledge on the function of ARL15, and strengthened the idea that ARL15 may act as small GTPase to interact and modify various types of transporters [97].

Gene ontology (GO) overrepresentation analysis of ARL15 BioID results suggest that ARL15 is involved in N-linked protein glycosylation. This pathway coincides with those observed in earlier studies evaluating the effects of small GTPase on glycosylation [115]. Protein glycosylation is a crucial and ubiquitous post-translational modification that can influence protein structure, stability, expression, and function [116-118]. Notably, BioID results revealed dolichol-phosphate mannosyltransferase subunit 1 (DPM1), dolichyl-diphospho-oligosaccharide (RPN1), lectin mannose binding 1 (LMAN1), and STT3 oligosaccharyltransferase complex catalytic subunits A and B (STT3A and STT3B) as the glycosylation-related proteins that have the highest relative binding abundance with ARL15. DPM1 transfers mannose from GDP-mannose (GDP-Man) to dolichol mannose (Dol-Man) in the synthesis of dolichol-phosphate mannose (Dol-P-Man) [119]. RPN1, which is exclusively found in the ER, is the component of N-oligosaccharyl transferase complex [120, 121]. This complex attaches high mannose oligosaccharides to N residues found in the nascent polypeptide chain consensus motif, this process is the first step of N-linked glycosylation [120, 121]. The LMAN1 functions as a glycoprotein transport cargo receptor that identifies sugar residues of glycoproteins and plays a crucial role in the transport or recycling of these proteins [122-124]. STT3A and STT3B are important for transferring the oligosaccharide in the process of glycosylation [125]. STT3A conveys glycan chains onto N residues of target proteins in the ER [126, 127]. STT3B is used to attach oligosaccharides onto N residues of target proteins [126, 127]. The binding between ARL15 and DPM1, RPN1, LMAN1, STT3A, and STT3B further support a role for ARL15 in the modification of protein glycosylation from ER to Golgi.

The functional interaction of ARL15 with CNNM proteins

Importantly, our Western blot results demonstrated that ARL15 affects the N-linked glycosylation of cyclin M 3 (CNNM3) (**Chapter 5**). The N-glycosylation of its homologue, CNNM2, is shown to be crucial in regulating CNNM2 plasma membrane expression [128]. Structurally, CNNM2 and CNNM3 have nearly 69% amino acid similarity [129], and the N-glycosylation site is conserved on their extracellular domain (CNNM2 N112 and CNNM3 N73) [128]. Interestingly, our mass spectrometry results identified ARL15 as the binding partner of CNNM2 in the DCT of the mouse kidney. Moreover, co-immunoprecipitation results demonstrated that ARL15 predominantly binds to the CBS2 motif of CNNM2.

Although the exact molecular function of CNNM proteins is still under debate [130, 131], it has been elucidated mutations in *CNNM2* lead to hypomagnesemia and CNNM

protein members are shown to be involved in Mg^{2+} transport [132, 133]. CNNM2 is localized to the basolateral side of the DCT, where is suggested to play a role in Mg^{2+} extrusion [128]. Here, TRPM6 (and TRPM7) channels are responsible for facilitating apical Mg^{2+} transport [134]. Interestingly, our BioID results present that ARL15 interacts with TRPM7. In a previous study by our group, 2-amino-ethoxydiphenyl borate, a non-selective TRPM6/7 inhibitor, was shown to abolish CNNM2-mediated $^{25}Mg^{2+}$ uptake in HEK293 cells [132]. Together, this suggests a connection between apical and basolateral Mg^{2+} transport mechanisms that may be simultaneously regulated by ARL15.

Our functional studies revealed that stable knockdown of ARL15 in various types of renal cell carcinoma cell lines resulted in increased $^{25}Mg^{2+}$ uptake and stable overexpression of ARL15 led to decreased $^{25}Mg^{2+}$ uptake (**Chapter 5**). Notably, in our cell surface expression experiments, neither ARL15 overexpression nor ARL15 knockdown affected the plasma membrane expression of CNNM3, which suggests that membrane trafficking of CNNM3 is not affected by ARL15. However, ARL15 knockdown resulted in disturbed glycosylation of CNNM3, suggesting that glycosylation of CNNM3 is important for its function. As a result of disturbed glycosylation CNNM3 may not be able to monitor or sense the intracellular Mg^{2+} concentration, which could lead to increased Mg^{2+} influx in ARL15 knockdown cells.

Recent studies showed that phosphatase of the regenerating liver (PRLs), which is a sub-family of the protein tyrosine phosphatases (PTP), interact with the extended loop of cystathionine-beta-synthase (CBS) 2 domain of CNNM3 [133, 135]. The binding between PRL2 and CNNM3 was increased under Mg^{2+} -deficient conditions, which led to an increase in the intracellular Mg^{2+} concentration [133]. Interestingly, Western blot results also showed that the expression of PRL2 is decreased in renal carcinoma cells overexpressing ARL15 (data not shown). The decreased expression of PRL2 could explain why ARL15 overexpression leads to decreased Mg^{2+} uptake in renal cell carcinoma cell lines (Figure 3).

Interestingly, ARL15 overexpression also decreased ATP production (**Chapter 5**). Mg^{2+} is used as a cofactor for multiple enzymes involved in ATP production, and ATP is bound to intracellular Mg^{2+} to form Mg-ATP as a biologically active molecule [96]. Hardy *et al.* demonstrated that intracellular ATP production is decreased upon cellular Mg^{2+} depletion, and that PRL expression is increased in response to low Mg^{2+} conditions [136]. In the same study, they addressed that this Mg^{2+} -dependent upregulation of PRL2 was activated by the AMPK/mTORC2 pathway [136], which could regulate cellular energy status [137].

Figure 3. Proposed mechanisms for the ARL15/CNNMs complex regulating Mg^{2+} transport.

In the DCT segment of the kidney, TRPM6/7 channels facilitate apical Mg^{2+} transport. Basolateral Mg^{2+} extrusion is regulated by CNNMs. When TRPM6/7 Mg^{2+} channels are closed, intracellular Mg^{2+} is low which will increase the expression levels of PRL2 (1) and concomitantly its binding to the CBS2 domain of CNNM (2). This will result in an increase of intracellular Mg^{2+} (3). Increased intracellular Mg^{2+} may increase ARL15 expression and/or activity (4), which will facilitate the glycosylation process of CNNM from endoplasmic reticulum (ER) to Golgi (5) to cell membrane (6). Increased intracellular ARL15 may act as negative feedback that decreases PRL2 expression, leading to less binding between CNNM and PRL2 (7), and a subsequent decrease in intracellular Mg^{2+} levels by Mg^{2+} extrusion via a yet unidentified transporter (8). ARL15, ADP ribosylation factor like GTPase 15; TRPM6/7, Transient receptor potential cation channel subfamily M member 6/7; CNNM, Cyclin M. PRL2, phosphatase of the regenerating liver 2.

Reduced Mg^{2+} levels stimulated mTORC2 activity, a downstream target of AMPK, which in turn was responsible for increasing PRL2 protein levels, without affecting mRNA status [136]. Inhibiting mTORC1 had no effect on the Mg^{2+} -dependent increase in PRL2 protein expression, while combined mTORC2 and mTORC1 inhibition decreased the expression

of PRL2 [136]. Given that ARL15 overexpression affected CNNM-mediated Mg^{2+} uptake and ATP production, the expression of ARL15 may indirectly regulate cellular metabolism.

Together, our study established ARL15 as a novel negative regulator of Mg^{2+} homeostasis by modulating the N-glycosylation of CNNMs.

Scientific impact and future perspectives

In **Chapter 2**, we found that DAPA treatment activates compensatory changes in the PT in diabetic mice by upregulating the expression of NaPi-2a and NHE3. This compensatory effect in the PT may lead to an imbalance in renal Na^+ handling in type 2 diabetes patients who suffer from hypertension. Future studies could focus on isolating and investigating urinary exosomes from type 2 diabetes patients to study the effect of SGLT2 inhibitors on BP by analyzing the expression of distal nephron Na^+ transporters such as NKCC2, NCC, and ENaC (α , β , γ). Then, the upregulated Na^+ transporter can be blocked by its inhibitor to improve BP control in type 2 diabetes patients.

In **Chapter 3**, we developed a Ca^{2+} -binding peptide with potential properties for further testing in kidney stone mouse model. A first study was started to induce kidney stone formation in C57BL/6J mice by administrating 1% (v/v) EG in their drinking water combined with a high or normal Ca^{2+} diet. While kidney stones were not observed in these mice, **Chapter 3** provided a solid theoretical basis and methodology reference on the knowledge related to kidney stone formation and the development of a novel treatment to prevent kidney stone disease.

In **Chapter 4**, we identified the novel Mg^{2+} -related *ARL15* gene and tested its function by the characterization of heterozygous knockout mice. *Ar15*^{+/-} mice displayed a normal phenotype, and showed no alterations in serum Mg^{2+} concentrations and 24 hours urinary Mg^{2+} excretion. In addition, the mRNA expression level of renal Mg^{2+} -, metabolism-, and membrane trafficking-related genes was not changed. These results suggest that ARL15 may not be involved in the regulation of renal electrolyte transport in the kidney. Future studies can focus on generating *Ar15* kidney-specific knockout mice and challenge these mice with Mg^{2+} -deficient diets to further reveal the function of ARL15 in the kidney.

In **Chapter 5**, we revealed the importance of ARL15 in maintaining Mg^{2+} homeostasis by interacting with CNNMs at their carboxy-terminal conserved CBS domains. ARL15 was shown to regulate complex N-glycosylation of CNNMs. Knockdown of ARL15 resulted in a significant increase of $^{25}Mg^{2+}$ uptake and ATP production in multiple kidney cancer cell lines. Our work provided new insights on how the interaction between ARL15 and CNNMs regulates N-glycosylation, Mg^{2+} transport, and ATP production. Future studies should reveal the interconnection between these processes, and demonstrate whether the ARL15-CNNM complex may provide new paths towards treating Mg^{2+} -related diseases.

In conclusion, elucidating the mechanisms involved in the maintenance of Na^+ , Ca^{2+} and Mg^{2+} homeostasis in both health and disease improves our understanding of their roles in diabetes, hypertension, kidney stones, and hypomagnesemia diseases.

Summary

Nederlandse samenvatting

Summary

Sodium (Na^+), magnesium (Mg^{2+}) and calcium (Ca^{2+}) homeostasis is critical for a variety of physiological processes in the human body. The kidney plays a crucial role in the regulation of this electrolyte balance. The concentration of serum Na^+ , Mg^{2+} , and Ca^{2+} is determined by the kidneys through the reabsorption of these electrolytes by transporters, ion channels and sensors in the proximal tubule (PT), thick ascending limb of loop of Henle (TAL), distal convoluted tubule (DCT) and connecting duct (CD) of the kidney. A disturbed electrolyte balance is associated with a variety of diseases such as hypertension, diabetes, renal carcinoma, and kidney stones. The aim of this thesis was I) to investigate the expression of Na^+ transporters in the kidney upon inhibiting the Na^+ -glucose transporter 2 (SGLT2) in the PT; II) to identify Ca^{2+} -binding peptides to reduce the urinary Ca^{2+} concentration and potentially prevent kidney stone formation; III) to study the novel urinary Mg^{2+} -related gene *ARL15* (ADP ribosylation factor like GTPase 15) in the kidney; and IV) to investigate how *ARL15* regulates Mg^{2+} transport by interacting with the cyclin and CBS domain divalent metal cation transport mediators (CNNMs) in the kidney.

Potential compensatory mechanisms of Na^+ transporters upon inhibition of SGLT2 in the proximal tubule

SGLT2 inhibitors have progressively attracted attention due to their function in increasing glucose excretion, ameliorating glycemic control and alleviating blood pressure. The latter is possibly due to the fact that SGLT2 inhibitors lead to natriuresis. However, the molecular mechanism is still unknown. In **Chapter 2**, diabetic mice were administered with the SGLT2 inhibitor dapagliflozin (DAPA) and the expression of renal Na^+ transporters/ion channels was studied. The diabetic mice exhibited increased blood glucose levels upon 18-day DAPA treatment, and mRNA levels of sodium-hydrogen antiporter 3 (*Nhe3*), and sodium-phosphate cotransporter (*Napi-2a*), were upregulated in kidneys of DAPA-treated mice. However, changes in expression of distal Na^+ transporters such as sodium-potassium-chloride cotransporter (NKCC2) and sodium-chloride cotransporter (NCC) in the TAL and DCT, respectively, were not detected. The results of this study proved that DAPA treatment results in compensatory changes in the PT of the kidney in diabetic mice.

Development of Ca^{2+} -binding peptides to prevent kidney stone formation in Henle's loop

Kidney stone disease (nephrolithiasis) is becoming a major medical concern in the world. Although medical therapies have largely improved nephrolithiasis treatment, the recurrence rate is still very high. Therefore, an improved and effective remedy to avoid kidney stone recurrence is needed. In **Chapter 3**, several Ca^{2+} -binding peptides were developed, based on the established Ca^{2+} -binding EF-hand domain. The Ca^{2+} -binding affinities of these peptides were investigated by circular dichroism demonstrating

dose-dependent response to CaCl_2 concentrations in the millimolar range for peptide 4 (Ac-DKNGDGYIDAAE-NH₃). This peptide did not result in cellular toxicity and exhibited minimal cellular uptake by proximal tubular human kidney 2 (HK-2) cells. A Ca^{2+} -binding affinity in the high millimolar range (2-10 mM) could allow for Ca^{2+} -binding in the pro-urine without affecting serum Ca^{2+} levels (1-2 mM). Future studies need to further optimize the Ca^{2+} -binding kinetics of the identified peptide. In order to investigate the biological function of this peptide in healthy mice and in a mouse model with kidney stones, C57BL/6J mice were administrated with 1% (v/v) ethylene glycol (EG) via drinking water and subsequently treated with either a normal Ca^{2+} diet (0.92% (w/w)) or a high Ca^{2+} diet (2% (w/w)) for 28 days. Yet, Ca^{2+} crystal deposition in the kidney was not detected in any of the conditions. **Chapter 3** demonstrated that Ca^{2+} -binding peptides can be used to bind Ca^{2+} in the physiologically relevant range. Optimized Ca^{2+} -binding peptides should be investigated in other mice models than C57BL/6J which better reflect kidney stone disease.

Fine tuning Mg^{2+} reabsorption in the distal convoluted tubule

Previous genome wide association studies (GWAS) identified the *ARL15* locus to be associated with urinary Mg^{2+} excretion in 9,099 individuals in seven European cohorts. *ARL15* is localized in the TAL and DCT of the kidney where it could be involved in renal Mg^{2+} reabsorption through regulating the channel activity of the Mg^{2+} channel TRPM6. In order to further understand the function of *ARL15*, we characterized *ARL15* and investigated its role in the kidney by using *Arl15* heterozygous (*Arl15*^{+/-}) mice in **Chapter 4**. Results demonstrated that *ARL15* belongs to the small GTPase superfamily and it is predicted to bind Mg^{2+} . The tissue expression pattern of *Arl15* showed that it is ubiquitously expressed and predominantly found in lung, inguinal fat, epididymal fat, spleen, testes and kidney. Homozygous *Arl15* knockout mice died after birth. By challenging *Arl15*^{+/-} mice with a high fat diet, we did not detect significant differences in the serum Mg^{2+} concentration and 24-hrs urinary Mg^{2+} excretion between *Arl15*^{+/+} and *Arl15*^{+/-} mice. In addition, there were significant changes detected in the mRNA expression levels of Mg^{2+} -related genes, metabolism-related genes, and membrane trafficking-related genes in the kidneys of either *Arl15*^{+/+} or *Arl15*^{+/-} mice on the high fat or low fat diets. In summary, our results suggest that *Arl15*^{+/-} mice have a normal phenotype, and exhibit no changes in renal Mg^{2+} handling.

ARL15 as a new binding partner of CNNM

By proximity-dependent biotin identification (BioID) and co-immunoprecipitation, we demonstrated that *ARL15* binds to proteins of the CNNM family. Interestingly, CNNMs have been reported to regulate Mg^{2+} transport at the basolateral membrane of the DCT. Subsequently, we investigated how *ARL15* regulates CNNM activity in **Chapter 5**. Immunostaining indicated that CNNM2 and *ARL15* co-localize along the basolateral

membrane of the DCT of mouse kidney. Co-immunoprecipitation demonstrated that ARL15 predominantly binds to the CBS2 domain of CNNMs. Our BioID results indicated that ARL15 is involved in N-linked glycosylation. Transient overexpression of ARL15 in human embryonic kidney 293 (HEK293) cells resulted in an increased N-glycosylation of CNNM3 proteins. The functional consequences of ARL15-dependent glycosylation were examined by $^{25}\text{Mg}^{2+}$ uptake experiments. We showed a significant decrease of $^{25}\text{Mg}^{2+}$ uptake upon overexpression of ARL15 and a significant increase of $^{25}\text{Mg}^{2+}$ uptake upon knockdown of ARL15 in multiple kidney cancer cell lines. Moreover, knockdown of ARL15 in renal cell carcinomas resulted in disturbed glycosylation of CNNM3. Altogether, our results established ARL15 as novel regulator of Mg^{2+} transport in the DCT.

This thesis provided new insights regarding compensatory mechanisms of Na^+ transporters in the PT upon inhibiting SGLT2, made the first step towards testing a novel approach in the treatment and prevention of kidney stones, and further revealed a novel regulatory mechanism of Mg^{2+} transport within the DCT. Together, this will help to understand more on the regulation of electrolyte handling in the various nephron segments.

Nederlandse samenvatting

De natrium- (Na^+), magnesium- (Mg^{2+}), en calcium (Ca^{2+}) -balans is cruciaal voor vele fysiologische processen in het menselijk lichaam. De hoeveelheid Na^+ , Mg^{2+} , en Ca^{2+} in het bloed wordt deels bepaald door de nieren. Heropname van deze mineralen vindt plaats in verschillende delen van de nier, waaronder de proximale tubulus, het dikke opstijgende been van de lis van Henle, het distaal convoluut en de verbindingsbuis. Een verstoorde mineraalbalans is geassocieerd met onder meer hoge bloeddruk, diabetes, nierkanker en nierstenen. Het doel van dit proefschrift was om: *I*) te onderzoeken wat het effect is van remming van de Na^+ -glucose transporter 2 (SGLT2) op de aanwezigheid van eiwitten betrokken bij de Na^+ heropname in de nier; *II*) Ca^{2+} -bindende eiwitfragmenten te ontwikkelen die zeer specifiek de Ca^{2+} concentratie in de urine kunnen verlagen om niersteenvorming te voorkomen; *III*) het nieuwe Mg^{2+} -gerelateerde gen ARL15 (ADP ribosylation factor like GTPase 15) in de nier te bestuderen; en *IV*) te achterhalen hoe ARL15 de Mg^{2+} heropname in de nier reguleert door middel van de interactie met cyclin en CBS domein divalent metal cation transport mediators (CNNMs).

Compensatoire mechanismen van Na^+ heropname door remming van SGLT2 in de proximale tubulus

De afgelopen decennia is er meer aandacht gekomen voor SGLT2 remmers door hun rol in het verbeteren van de bloedsuikerspiegel en het verlagen van de bloeddruk. SGLT2 remmers verlagen de bloeddruk door een verhoogde uitscheiding van Na^+ in de urine, ook wel natriurese genoemd. In **hoofdstuk 2** kregen muizen met diabetes de SGLT2 remmer dapagliflozin (DAPA) toegediend en werd de aanwezigheid van genen en eiwitten relevant voor Na^+ heropname in de nier bestudeerd. De muizen met diabetes vertoonden een verhoogde glucosewaarde in het bloed die sterk verlaagd was na een 18-daagse behandeling met DAPA. Om de effecten van SGLT2 remmers op Na^+ heropname in de nier te bestuderen, zijn de eiwitten die Na^+ opnemen in de verschillende delen van de nier in kaart gebracht. De aanwezigheid van de genen natrium-waterstof uitwisselaar 3 (*Nhe3*) en natrium-fosfaat cotransporter (*Napi-2a*) in de proximale tubulus was verhoogd in DAPA-behandelde muizen. Er werden geen verschillen waargenomen in de aanwezigheid van de genen *Nkcc2* en *Ncc* (belangrijk voor het transport van Na^+ in de lis van Henle en het distaal convoluut) tussen DAPA-behandelde en onbehandelde muizen met diabetes. De resultaten van deze studie bewijzen dat DAPA-behandeling zorgt voor verhoging van compensatoire eiwitten die betrokken zijn bij Na^+ heropname in de proximale tubulus van de nier in muizen met diabetes.

Ontwikkeling van Ca^{2+} -bindende peptiden om niersteenformatie te voorkomen in de lis van Henle

Nierstenen (nefrolithiase) zijn een wereldwijd toenemend medisch probleem. Patienten die nierstenen hebben gehad, hebben een grote kans op terugkeer ondanks de verbeterde behandeling. Een effectievere methode om nierstenen te voorkomen is dan ook noodzakelijk. In **hoofdstuk 3** zijn Ca^{2+} -bindende eiwitfragmenten ontwikkeld. Hiervoor is gebruikt gemaakt van de structuur van een natuurlijk Ca^{2+} -bindend eiwit, het zogenaamde EF-hand domein. De binding van Ca^{2+} aan deze eiwitfragmenten is onderzocht door gebruik te maken van circulair dichroïsme spectroscopie. Deze metingen lieten een dosisafhankelijk effect zien van de calciumconcentratie op eiwitfragment 4 (Ac-DKNGDGYIDAAE-NH₃). Daarnaast werd aangetoond dat dit eiwitfragment niet resulteerde in cellulaire toxiciteit, en het vertoonde slechts minimale cellulaire opname in proximale tubulus humane nier 2 (HK-2) cellen. Ca^{2+} -binding aan dit eiwitfragment bij concentraties in de hoge millimolaire eenheid (2-10 mM) zou Ca^{2+} weg kunnen vangen in de voorurine zonder de Ca^{2+} waarde in het bloed te beïnvloeden (1-2 mM). Verder onderzoek is nodig om de binding van Ca^{2+} aan het beoogde eiwitfragment te optimaliseren. Om de biologische rol van dit eiwitfragment te onderzoeken, zijn diersmodellen met nierstenen nodig. Hiertoe werden muizen behandeld met 1% (v/v) ethyleenglycol (EG) in het drinkwater en eveneens een Ca^{2+} -rijk dieet gevoerd gedurende 28 dagen. Echter, kristalafzetting in de nier werd niet waargenomen. Concluderend, **hoofdstuk 3** laat zien dat Ca^{2+} -bindende eiwitfragmenten gebruikt kunnen worden om Ca^{2+} te binden binnen fysiologische concentraties. Geoptimaliseerde Ca^{2+} -bindende eiwitfragmenten dienen getest te worden in alternatieve muismodellen waarin nierstenen beter vormen dan in de hier gepresenteerde studie.

Het nauwkeurig instellen van de Mg^{2+} heropname in het distaal convoluut

Eerdere genoom-brede associatiestudies (GWAS) hebben een associatie geïdentificeerd tussen ARL15 en de urinaire Mg^{2+} uitscheiding in zeven Europese cohorten van totaal 9.099 individuen. ARL15 is aanwezig in de lis van Henle en het distaal convoluut van de nier, waar het mogelijkwerwijs betrokken is bij de heropname van Mg^{2+} . ARL15 behoort tot de superfamilie kleine GTPases en bindt mogelijk Mg^{2+} . Om de functie van ARL15 in de nier beter te begrijpen werden in **hoofdstuk 4** muizen gebruikt die over een heterozygote uitschakeling van het *Arl15* gen beschikken (*Arl15*^{+/-}). Muizen zonder het *Arl15* gen sterven na geboorte. *Arl15* wordt aangemaakt in meerdere weefsels, en met name in de longen, buikvet, milt, testis en nieren. *Arl15*^{+/-} muizen die blootgesteld werden aan een vetrijk dieet vertoonden geen significante veranderingen in de hoeveelheid Mg^{2+} in het bloedplasma of in de uitscheiding van Mg^{2+} in de urine gedurende 24-uur, ten opzichte van gezonde muizen. Daarnaast werden er geen significante verschillen waargenomen in aanwezigheid van genen betrokken bij de Mg^{2+} -balans, bij metabolisme of bij membraantransport tussen de nieren van *Arl15*^{+/-} en gezonde muizen op een

vetrijk of vetarm dieet. Samenvattend, onze resultaten tonen aan dat *Arl15*^{+/-} muizen beschikken over vergelijkbare erfelijke eigenschappen als gezonde muizen, en dat zij geen abnormaliteiten vertonen wat betreft de Mg^{2+} heropname in de nier.

ARL15 als nieuwe interactiepartner van CNNM

Door gebruik te maken van biochemische bindingstudies, waaronder de zogeheten (nabijheid-afhankelijke) biotine identificatie (BioID) en co-immunoprecipitatie, hebben wij aan kunnen tonen dat ARL15 aan eiwitten uit de CNNM-familie bindt. CNNMs staan erom bekend het Mg^{2+} transport te regelen aan het basolaterale membraan van niercellen. In **hoofdstuk 5** is onderzocht hoe ARL15 de activiteit van deze CNNM eiwitten reguleert. Met behulp van immunohistochemische kleuringen van nieren van de muis werd aangetoond dat CNNM2 en ARL15 samen aanwezig zijn in distaal convoluutcellen. Uit co-immunoprecipitatie experimenten bleek dat ARL15 voornamelijk bindt met het CBS2 domein van CNNM. Onze BioID resultaten suggereren dat ARL15 betrokken is bij N-gebonden glycosylering. Een verhoogde aanwezigheid van ARL15 resulteerde in een verhoogde glycosylering van CNNM3 eiwitten in humane embryonale niercellen (HEK293). De functionele consequenties van ARL15-afhankelijke glycosylering werden onderzocht middels experimenten met een stabiel ²⁵Mg isotoop. Er was een significante vermindering van Mg^{2+} opname bij verhoogde aanwezigheid van ARL15 in meerdere nierkankercellijnen, en een hogere Mg^{2+} opname wanneer ARL15 was uitgeschakeld. Bovendien was er een verstoorde glycosylering van CNNM3 bij uitschakeling van ARL15. Tezamen suggereren onze resultaten dat ARL15 het Mg^{2+} transport in het distaal convoluut reguleert door de activiteit van CNNM eiwitten te bepalen.

Concluderend hebben de studies beschreven in dit proefschrift geleid tot nieuwe inzichten in de mechanismen achter Na^+ heropname in de proximale tubulus bij het gebruik van SGLT2 remmers. Daarnaast is een eerste stap gezet in het opzetten van een vernieuwende benadering voor de preventie van nierstenen. Tot slot is er een nieuw regulatiemechanisme van Mg^{2+} heropname in het distaal convoluut aan het licht gebracht.

Curriculum vitae

Chao Ma was born in Jilin, China, on the 17th of October 1988. After graduating from high school, he obtained his bachelor with a major in Resource and Environmental Sciences at Jilin Agriculture University in Jilin, China. In 2012, he decided to pursue his interest in life science and joined Professor Shuping Zhang's lab at Tsinghua University in Beijing, China. During his master study, he focused on examining the tissue distribution of Renalase in *ApoE*^{-/-} mice fed a high-fat diet and the effect of valsartan on the expression of Renalase. He found that Renalase is a potential-related gene of lipid

metabolism and atherosclerosis, and it may be the possible molecular target of valsartan to help stabilize atherosclerotic plaque. His master research consisted of studying the function of a novel Mitochondria-localized Glutamine Acid Rich Protein (MGARP) in the development of the retina, with emphasis on photoreceptor cells, by using in utero electroporation in *Mgapr*^{-/-} embryonic mice. In 2016, Chao joined the department of Physiology at the Radboud university medical center (Radboudumc) as a PhD candidate. Under the supervision of Prof. dr. Joost Hoenderop, Dr. Jeroen de Baaij and Dr. Jenny van der Wijst, his research focused on investigating the effect of dapagliflozin treatment on the expression of renal sodium transporters/channels on high-fat diet diabetic mice. This part of work provides insights on the treatment of both hypertension and diabetes in Type 2 diabetes patients. In another study, he developed several small peptides with optimized Ca²⁺-binding affinity to act as Ca²⁺ buffers in Henle's loop, without affecting serum Ca²⁺ levels. This may provide the first evidence for an effective approach to further study treatment and prevention of kidney stones. His PhD research work also consists of studying the functional implication of ARL15 for CNNMs-mediated Mg²⁺ transport. Chao presented his work by oral and poster presentations at scientific conferences. In 2019, he received the travel grant to visit the American Society of Nephrology meeting in Washington, D.C., USA. Additionally, Chao successfully completed the PhD training program of the RIMLS graduate school and supervised four master students and five undergraduate students from Biomedical Sciences and Medical Biology studies.

Research data management

The data generated during my PhD project at the Radboudumc were documented according to the Findable, Accessible, Interoperable and Reusable (FAIR) guiding principles.¹ All the primary and processed data obtained during my PhD work are stored on the local digital servers which belong to the department of Physiology and Radboudumc. In addition, all data were accessible on Labguru, an electronic lab book, which is managed and supported by the Information and Communication Technology (ICT) unit of Radboudumc and daily backed-up on local Radboudumc servers. The animal studies described in **Chapter 2, Chapters 3 and 4** were approved by the University of Ulster Animal Ethics Review Committee, the Animal Ethics Board and the Central Animal Laboratory of the Radboudumc and the MRC Harwell Institute Ethical Review Committee and the MRC Harwell Animal Welfare, all in agreement with the Experiments on Animals Act (Wet op de dierproeven, Wod). To make sure the data is accessible to the associated staff, all data (including raw data, descriptive files, figures, and file names) is stored and archived in accordance with the protocols of the department of Physiology.

Yes, approved, this is the title of the email I got from my supervisor, professor, and also my friend, Prof. Dr. Joost Hoenderop, when my thesis was approved by thesis committee. With some pride, I am very happy with my thesis and my work. In my time in physiology, I have learned and matured a lot both scientifically and personally and I am very grateful to many people who helped me along the way. In this chapter, I would therefore like to express my gratitude to my supervisors, colleagues, collaborators, friends, and family who motivated, helped, and supported me and thus, in their own way, contributed to this thesis.

First and foremost, I would like to express my appreciation to Prof. Dr. Joost Hoenderop, Prof Dr. René Bindels, and my co-promoter Dr. Jeroen de Baaij and Dr. Jenny Van der Wijst for their guidance and support throughout my 4 years work in the physiology department. **Joost**, thank you for helping me so much in these years. Over the years, I learned a lot from you. If I use one word to describe you, I will use discipline to describe you. I always believe that discipline is the most important value and character that a successful man should have. If I use five words to describe you, I will use discipline, hardworking, leadership, determined, and optimistic to describe you. You always start to work early in the morning. Most of the time, I can always receive your email reply very fast wherever you are in the world. We can always get support from you. Whenever we have difficulties, you can always give us useful suggestions and find positive perspectives. You are such a hardworking man who set an excellent role model for us. Every time I feel tired, you motivated me to have the energy to work again and never give up. Thank you for checking my thesis point by point. I feel so touched that you even helped me to find my mistakes in my references, there are around 500 references in total in my thesis. Thanks for the ideas and inputs you provided to my PhD study, and your strong leadership in the work, and your advice to my life. I am very happy to work and talk with you both at work and after work. I never have the feeling that you are my professor or boss, however, I always regard you as a very good friend who always support me, cheer up me, and steer me to the correct direction both scientifically and personally. Therefore, I am not surprised that you won the University Teaching Prize, and you also made a great contribution to the physiology study and published a lot of great papers in top journals. You are a perfect example of showing that you can be excellent in everything you put effort into. **Jeroen**, it's really nice that I start to work together with you in my second year. You are such an amazing and smart guy with unbelievable leadership. Communicating with you is such a cozy thing that I enjoyed a lot. Thank you for guiding me for the ARL15 and CNM study. We finally made it into a story. You give me so many good ideas and inspired me so much. I still remember in the CNM meeting, when I was giving a presentation, you and Joost gave me so many eye contacts and inspired me a lot. I have the feeling that you and Joost are even more nervous than me. At that point, I feel so happy and lucky to have two supervisors like you two people. I do enjoy the nice talks with you at the lunch time, work discussion, drinking beers in Nijmegen, having Chinese food, and we had very a nice time in Washington D.C in the ASN meeting. **Jenny**, you started to supervise me in my third

year, you are so nice, patience, and sweet. You are always there to help us and listen to us. I do enjoy the nice talks with you in the coffee break time, lunch time, experiments time, work discussion, and the amazing dinner at your home. You also give me a lot of good ideas on my projects. Now, I also learned a lot of chemistry knowledge through our kidney stone project. We met almost weekly in the last few months to talk about my thesis. Thank you so much for helping me to correct the structure of the thesis, mistakes, and providing great ideas on how to make the figures better. Now, I am much more confident in writing than before. **René**, thank you for your great vision, leadership, and your extraordinary ability to our RIMLS institute and our department. We appreciate the efforts taken by you. We love our human oriented institute and department so much. Especially as foreigners, I never feel lonely. I really enjoy the talks with you in the work meetings and the dinner in the ASN meeting.

Dr. **Jo Zhou**, thank you for mentoring me for four years. In these four years, you gave me a lot of useful suggestions and advices to help me to master my PhD work and my future career choice. I do enjoy the nice talks with you. Thank you very much.

The collaborations with other research groups have been of great benefit for my work in my PhD study. I am grateful to all of the people who were directly or indirectly involved in and contributed to my projects. Prof. Dr. **Michel Tremblay**, thank you for your inputs, ideas, and scientific discussions on the ARL15 and CNNM project! It has been wonderful to work together with your team. Your enthusiasm in science inspired me a lot. Also **Eugene**, it's really nice to collaborate with you for our ARL15 and CNNM story. You are a hard worker and an extremely motivated guy. We finally made our ARL15 and CNNM project into a very nice story and good luck with your PhD in Montreal. **Serge**, you made a lot of unbelievable contributions to CNNM and PRL study, I am really happy to see that you addressed a detailed mechanism study of ATP, PRL, and AMPK/mTORC2 pathway at various levels, which will definitely boost the study of magnesium, PRL, and CNNM. I am looking forward to seeing more and more papers from you. Dr. **Alfonso Martínez de la Cruz**, thanks for all of the works you did for the structure biology part of the ARL15 and CNNM paper. I do enjoy the nice scientific discussion, nice talks with you in our zoom meeting and CNNM meeting. Structure biologists are our best friends, your knowledge and findings on the structure of CNNM, ARL15, and PRL will always be highly appreciated. Dr. **Roger Cox** and Dr. **Ying Bai**, thanks for providing us with *Arl15^{+/-}* mice samples, these samples boost our study and navigated us to the correct direction. We will definitely combine all of our data and make it into a nice story. Prof. Dr. **Roland Brock** and **Sander Van Asbeck**, thanks for your technical supports and suggestions for my kidney stone project.

Luke, it's really nice to meet you in the Netherlands. In the past few years, we went to so many places and had so many nice memories. The nice beer, food, and traveling in Rotterdam, Arnhem, Haarlem, Nijmegen, and Doetinchem. In my first year, you helped me so much in my SGLT2 project, helping me to involve in European lifestyle, and my English. Through time, we develop very good friendships, you became a true friend, and

of course now my paranimf, and we still keep in touch although you left our department. Thanks for your support in these years, especially your help in polishing my cover letter and CV for my postdoc position. Thank you for your nice present which will definitely help me to know more about Los Angeles very fast. By the way, I still remember our plan to travel in the USA and to go to visit Marco in Mexico next year, hope to see you soon. I wish you all the best for your life in the Netherlands with **Emma**. And I am sure that we will keep in touch and keep seeing each other. Mi amigos, **Paco, Juan, Sara, Maria**, you guys have very strong postdoc power. **Paco**, you are a very funny guy, I still remember we can't understand each other's English in the beginning, and we always need Eric V or Caro to be our translator, but this did not affect our friendship. I do enjoy the nice time with you playing football, funny talks, watching the World cup, yearly beer night, and your supports in my PhD study. I am very happy that you are enjoying your nice life with your wife and your son **Daan A**. But, by the way, it seems that we still can't understand each other's English, even until now. **Juan**, I always have the feeling that you are on your way to travelling or on your way back from travelling. We had a nice time in the Düsseldorf Christmas market and enjoyed the nice beer and wine, Germany Schweinhaxen, and Japanese noodles in Düsseldorf. You are my true friend, and of course now my paranimf. I do enjoy the nice talks with you at dinner time after work, and thanks for your traveling suggestions on my tour around Europe. We should always keep in touch, and I am sure I will meet you again in California and China. I hope you will enjoy your life in either Europe or Argentina in the future. **Sara**, I do enjoy the nice talks with you at lunch time, drinking beers at Olivier in Utrecht with the gang and your boyfriend. You are a very outgoing lady who can always cheer people up. I always have the feeling that you can always give me a lot of useful suggestions and helps whenever I need help. Thanks for your useful and good suggestions for my postdoc searching. I am quite happy that you are enjoying a nice time in Switzerland. Like you said science is small, I am sure we will meet each other one day. **Maria**, my neighbor in my last few months in our department. We also had a lot of nice talks at lunch time. Thank you for your supports and kind suggestions for my PhD work and postdoc searching. I wish you all the best for the future; you've been and always will be a great friend to me. **Sami** and **Eric V**, the Cilia Team. **Sami**, we had so many talks outside and inside the lab, you are a very good company after work in the lab. Both of us are foreigners in the lab, so we always support each other and help each other. I do enjoy the travelling with you, playing football with you. Thanks for the nice suggestions you gave me in the Netherlands. In my last few days in the Netherlands, we met in Maastricht and made a lot of nice pictures, all of these are very nice memories of my life. I am very happy with you on your success in your postdoc career by winning many grants and publishing many papers. In the second year of my PhD, we made the plan to travel to Paris, but later, we didn't manage to do it. In two months, you will come to the USA; we should travel in the USA as we planned in Amsterdam. I hope all is going well for you, and we can always have a chat whenever we want to talk to each other. **Eric V**, my dear friend, we had

a lot of nice memories together. Talking together during coffee breaks, drinking beers at Olivier in Utrecht, Arnhem, and my place, attending your marriage party and gender reveal party, and the yearly drink in Arnhem. We also had a very nice time in Washington in the ASN meeting. Thank you for guiding me around Washington, and we made many nice pictures together. All of these consist of my good memories in the Netherlands. I am very happy that you are enjoying your new job, your life with **Mirte** and **Lotte V**. I wish you and your family all the best for the future and I am sure that we will keep in touch and keep seeing each other. You are always welcome wherever I am living. **Hacene**, it's also very nice to meet you in the Netherlands. We both work in the metabolism team. It has been wonderful to work together with you during these past few years although we didn't work together directly. You were a great company inside the lab after work and outside the lab on the weekends. We explored Nijmegen so much and made a lot of nice pictures. Thanks for your support in these years. I am very happy that you are enjoying your time with your family and your work in Algeria. You've been and always will be a great friend to me. I wish you all the best for your PhD and your future and I am always happy to hear from you and talk to you. **Valentina**, a hard worker, and extremely motivated PhD. You were a great company in the lab in the evening and weekend. Although we haven't worked directly together on a project, yet I cherish good memories with you such as the nice talks during the breaks, dinner time, drinking beers at Olivier in Utrecht, and Arnhem. I wish you all the best for your PhD and scientific career. **Marco**, My Spanish learning was initiated by you. I still remember the first word you taught me was Adios, mi amigo. Together with you, and Luke, we went to many bars and restaurants in Nijmegen. Hopefully, Luke and I can manage to go to visit you in Mexico. I wish you all the best for your work and life. **Steef**, we work in the same team, you are a very smart guy with critical thinking. I enjoyed the nice talks with you and thanks for your suggestions on my projects. It has been great to work together with you in the past few years. I had a great time sharing my data and having scientific discussions with you. **Omar**, you are the first people who went to pick me up in Nijmegen, and introduced the people in the lab to me. Your enthusiasm and sense of humor did motivate me a lot at the beginning of my PhD study. It has been nice to work together with you in the sodium team. **Lisanne**, you are a very warmhearted girl. I do enjoy the nice talks with you in the coffee breaks, and I hope that you can find a good job, and always be happy. **Gijs**, you are a very funny guy. I found that you always have a lot of topics to talk with different people. It was nice to work with you to learn more about CNNM protein, and we are making a lot of progress on it. Thank you for your immunocytochemistry results for our ARL15 and CNNM story, and also thanks for giving a lot of good suggestions on improving the manuscript. It was really a lot of fun to have the CNNM meeting with you, drink beers after the meeting, and the nice talks with the collaborators who are working very hard on elucidating the function of CNNM. **Lynette**, ARL15 is a great protein, I am very happy to work together with you to investigate the function of ARL15. It has been a lot of fun to share the data, have scientific dis-

cussion with you. I am very looking forward to seeing your great story on ARL15 kidney-specific knockout mice. **Lotte**, we may not have worked directly together on a project, yet we both study novel genes related to hypomagnesium. I am very looking forward to your pinkbar protein stories. I do like the nice talks with you on the weekend, coffee break time, lunch time, and the glow festival in Eindhoven. You still need to tell more about your stories and experience in China. With many colleagues, I have had the privilege to develop amazing friendships. Just like those people mentioned above, this is also true for **Michael, Sjoerd, Mark, and Eric B.** Together with you guys, **Luke, Paco, and Eric V**, we have the yearly beer drink event in Arnhem before Christmas, lots of nice talks, food & drinks together, we had a lot of fun times and I hope they continue!

Femke, thank you so very much for helping me in the molecular works. I do enjoy our nice talks in the coffee break, sharing my data with you, the great inputs from you, and the nice scientific talks in the lab meeting. You've been and always will be a great friend to me. **Caro**, you also helped me a lot on animal studies and the staining. It has been great to work together with you and be your neighbors in my first two years. I do enjoy the nice talks with you at lunch time, coffee break times, and physiology events. You act like a running sun who always bright other people's life. **Irene**, thank you for making our department so organized, and the items we ordered delivered in good condition. I also appreciate the greetings from you through Facebook at the beginning of this year. **Rosanne**, thanks for helping me to arrange everything at the beginning of my PhD work. You made my life much easier. **Rachel, Véronique, Judith, and Janneke**, thanks for arranging the meetings, events, and paperwork for our department. Your contributions are highly appreciated. **Jojanneke**, thanks for organizing the teaching, I feel very happy and honored to be involved in the teaching. **Nicolai**, I enjoy the nice talks with you in the meetings and thank you for your tips and suggestions on my career choice.

Sidra, Milou, Shirin, and Sanedy, you guys are unbelievably good, smart, and hard-working master students. I am so honored to supervise you. Thanks for the contributions you made to the ARL15 and CNNM story, and the kidney stone story.

Furthermore, I would like to express my appreciation to all the rest who bring/brought our department to the 'next level', **Andreas, Elja, Charlotte, Claudia, Mohammad, Daan, Ellen, Frans, Kim, Laura, Niky, Barnabas, Margo, Marjolein, Anique, Lara, Wouter, Peter, Selma, and Theun**, and all the people from Integrative Physiology and anyone that I might have forgotten!

Tommy, my language partner in Tsinghua University, you are the first foreigner I met in Beijing, and I always believed that I wouldn't come to the Netherlands if I didn't meet in China. Our friendship starts in China, and we had a lot of nice talks in Tsinghua University and in Beijing. I wish you all the best for your future and your life in the Netherlands and hope we keep on seeing and messaging each other. You've been and always will be a great friend to me, our time together in China and the Netherlands were unbelievably great! Thank you for recommending me the Dutch universities, then, I have the oppor-

tunities to come to the Netherlands where I met a lot of amazing people and had an incredibly great memory. I will always cherish my memories in the Netherlands in my life.

Brazilian Omar, it was super nice to meet you on the 7th floor of RIMLS. We had a lot of nice talks after work and had a lot of good time in Nijmegen and Maastricht. You are a very hardworking and motivated PhD; I wish you all the best for your life in the Netherlands and your research career.

Hans, my landlord, I am the only guy who stayed at your place for more than one year, and it's 4 years in total in the end. We had a lot of nice memories in Nijmegen and Germany. Thanks for your help, suggestions, nice dinners, and supports in these four years. I wish you all the best for your life. You are always welcome wherever I live.

宋春喜大哥，我常常想，我们是什么样的缘分，能在荷兰交到您这个忘年交，记得一次吃饭，您说过您80年代在我的老家当过兵，我想只有用缘分来解释我们在荷兰的相遇。您通过自己的努力，在荷兰有了今日的成就，祝您的公司更上一层楼。我也随时会支持您并帮助您实现将传统中医发扬光大的梦想。

张老师，感谢您在我读硕士时候的教导，您对科研的严谨认真，一直影响着我，感谢您的培养。周明学师兄，感谢你这么多年来帮助，是你带我入了生命科学的大门，在后来又给了我很多的帮助，永远都记得当年在北京时候，你给我的帮助。贾利云师姐，感谢你在张老师实验室教我做电转，免疫组化，你是一个好老师，很开心，你在郑州找到了自己的生活和工作方向。杨慧朋师兄，感谢你在分子生物学上对我的帮助，我们一起研究MGARP在视网膜中的作用，与你一起做实验，探讨科研问题，我很开心。李凌丹师姐，虽然我们没有直接的共同做过一个课题，但是，在实验室遇到你这个老乡真的很开心，我很喜欢午饭时，以及平时和你关于人生的探讨。吴放师兄，感谢你在清华对我的帮助，无论是生活上，学术上，你都给了我无尽的帮助。梁桐师兄，我们共同研究MGARP的作用，后来，一起来了欧洲，感谢你在瑞士的照顾，也恭喜你将自己的工作发表在顶级期刊上。李蕊师姐，我和梁桐师兄紧随你的步伐，来了欧洲，很开心你在欧洲找到自己的幸福。刘雨桐师妹，我们一起发表了很多文章，感谢你的帮助以及提供的想法。

苏卫朋，李杨，刘耀先，你们是我多年的挚友，每次有什么不开心的事情都会找你们聊天，你们都会给我很多鼓励与帮助，很感激你们，很开心遇到过你们，希望我们的友谊可以永存。

同时也要感激我的家人们，你们给了我无数的关爱与鼓励，你们也是我努力奋斗的动力源泉。

爸爸，妈妈，谢谢你们，感谢你们为了我的坚持，我的梦想，无条件的支持我。虽然我是家中唯一的孩子，但是，您们从没有限制过我对梦想的追求。虽然，您们担心我在海外会遇到各种坎坷，尤其还在异国他乡，没有父母的陪伴。但是，我已经长大，不能一直像孩童时期依偎在您们的身边，我要独身一人寻找更加宽阔的空间，创造人生的辉煌。正是因为昨天的分离，才有了我今天不一样的人生！感谢你们一直鼓励我，支持我，相信我，由于学习的原因，多年在海外不能在您们身边陪伴，每次想到这里，我都心有愧疚，所以，我常告诫自己要努力变得越来越优秀，成为父母的骄傲，不辜负您们对我的期待。最后，感激所有未能提及的，但是对我直接或间接有过帮助的人，感谢你们。
